38. Non flasque quasi-coherent sheaf associated to injective module
39. A non-separated flat group scheme

This is a chapter of the Stacks Project, version 7e38297, compiled on Feb 17, 2015.
1. Introduction

This chapter will contain examples which illuminate the theory.

2. An empty limit

This example is due to Waterhouse, see [Wat72]. Let $S$ be an uncountable set. For every finite subset $T \subset S$ consider the set $M_T$ of injective maps $T \to \mathbb{N}$. For $T \subset T' \subset S$ finite the restriction $M_{T'} \to M_T$ is surjective. Thus we have a directed inverse system with surjective transition maps. But $\lim M_T = \emptyset$ as an element in the limit would define an injective map $S \to \mathbb{N}$.

3. A zero limit

Let $(S_i)_{i \in I}$ be a directed inverse system of nonempty sets with surjective transition maps and with $\lim S_i = \emptyset$, see Section 2. Let $K$ be a field and set

$$V_i = \bigoplus_{s \in S_i} K$$
EXAMPLES 3

Then the transition maps \( V_i \to V_j \) are surjective for \( i \geq j \). However, \( \lim V_i = 0 \).

Namely, if \( v = (v_i) \) is an element of the limit, then the support of \( v_i \) would be a finite subset \( T_i \subset S_i \) with \( \lim T_i \neq \emptyset \), see Categories, Lemma 21.5.

For each \( i \) consider the unique \( K \)-linear map \( V_i \to K \) which sends each basis vector \( s \in S_i \) to 1. Let \( W_i \subset V_i \) be the kernel. Then

\[
0 \to (W_i) \to (V_i) \to (K) \to 0
\]

is a nonsplit short exact sequence of inverse systems of vector spaces over the directed partially ordered set \( I \). Hence \( W_i \) is a directed system of \( K \)-vector spaces with surjective transition maps, vanishing limit, and nonvanishing \( R_1^\lim \).

4. Non-quasi-compact inverse limit of quasi-compact spaces

Let \( \mathbb{N} \) denote the set of natural numbers. For every integer \( n \), let \( I_n \) denote the set of all natural numbers \( > n \). Define \( T_n \) to be the unique topology on \( \mathbb{N} \) with basis \( \{1\}, \ldots, \{n\}, I_n \). Denote by \( X_n \) the topological space \((\mathbb{N}, T_n)\). For each \( m < n \), the identity map,

\[
f_{n,m} : X_n \longrightarrow X_m
\]

is continuous. Obviously for \( m < n < p \), the composition \( f_{p,n} \circ f_{n,m} \) equals \( f_{p,m} \). So \( ((X_n), (f_{n,m})) \) is a directed inverse system of quasi-compact topological spaces.

Let \( T \) be the discrete topology on \( \mathbb{N} \), and let \( X \) be \((\mathbb{N}, T)\). Then for every integer \( n \), the identity map,

\[
f_n : X \longrightarrow X_n
\]

is continuous. We claim that this is the inverse limit of the directed system above. Let \((Y, S)\) be any topological space. For every integer \( n \), let

\[
g_n : (Y, S) \longrightarrow (\mathbb{N}, T_n)
\]

be a continuous map. Assume that for every \( m < n \) we have \( f_{n,m} \circ g_n = g_m \), i.e., the system \((g_n)\) is compatible with the directed system above. In particular, all of the set maps \( g_n \) are equal to a common set map

\[
g : Y \longrightarrow \mathbb{N}.
\]

Moreover, for every integer \( n \), since \( \{n\} \) is open in \( X_n \), also \( g^{-1}(\{n\}) = g_n^{-1}(\{n\}) \) is open in \( Y \). Therefore the set map \( g \) is continuous for the topology \( S \) on \( Y \) and the topology \( T \) on \( \mathbb{N} \). Thus \( (X, (f_n)) \) is the inverse limit of the directed system above.

However, clearly \( X \) is not quasi-compact, since the infinite open covering by singleton sets has no inverse limit.

**Lemma 4.1.** There exists an inverse system of quasi-compact topological spaces over \( \mathbb{N} \) whose limit is not quasi-compact.

**Proof.** See discussion above. \( \square \)
5. A nonintegral connected scheme whose local rings are domains

We give an example of an affine scheme $X = \text{Spec}(A)$ which is connected, all of whose local rings are domains, but which is not integral. Connectedness of $X$ means $A$ has no nontrivial idempotents, see Algebra, Lemma \ref{lem-17-2}. The local rings of $X$ are domains if, whenever $fg = 0$ in $A$, every point of $X$ has a neighborhood where either $f$ or $g$ vanishes. As long as $A$ is not a domain, then $X$ is not integral (Properties, Definition \ref{def-3.1}).

Roughly speaking, the construction is as follows: let $X_0$ be the cross (the union of coordinate axes) on the affine plane. Then let $X_1$ be the (reduced) full preimage of $X_0$ on the blow-up of the plane ($X_1$ has three rational components forming a chain). Then blow up the resulting surface at the two singularities of $X_1$, and let $X_2$ be the reduced preimage of $X_1$ (which has five rational components), etc. Take $X$ to be the inverse limit. The only problem with this construction is that blow-ups glue in a projective line, so $X_1$ is not affine. Let us correct this by glueing in an affine line instead (so our scheme will be an open subset in what was described above).

Here is a completely algebraic construction: For every $k \geq 0$, let $A_k$ be the following ring: its elements are collections of polynomials $p_i \in C[x]$ where $i = 0, \ldots, 2^k$ such that $p_i(1) = p_{i+1}(0)$. Set $X_k = \text{Spec}(A_k)$. Observe that $X_k$ is a union of $2^k + 1$ affine lines that meet transversally in a chain. Define a ring homomorphism $A_k \to A_{k+1}$ by

$$(p_0, \ldots, p_{2^k}) \mapsto (p_0, p_0(1), p_1, p_1(1), \ldots, p_{2^k}),$$

in other words, every other polynomial is constant. This identifies $A_k$ with a subring of $A_{k+1}$. Let $A$ be the direct limit of $A_k$ (basically, their union). Set $X = \text{Spec}(A)$. For every $k$, we have a natural embedding $A_k \to A$, that is, a map $X \to X_k$. Each $A_k$ is connected but not integral; this implies that $A$ is connected but not integral. It remains to show that the local rings of $A$ are domains.

Take $f, g \in A$ with $fg = 0$ and $x \in X$. Let us construct a neighborhood of $x$ on which one of $f$ and $g$ vanishes. Choose $k$ such that $f, g \in A_{k-1}$ (note the $k - 1$ index). Let $y$ be the image of $x$ in $X_k$. It suffices to prove that $y$ has a neighborhood on which either $f$ or $g$ viewed as sections of $\mathcal{O}_{X_k}$ vanishes. If $y$ is a smooth point of $X_k$, that is, it lies on only one of the $2^k + 1$ lines, this is obvious. We can therefore assume that $y$ is one of the $2^k$ singular points, so two components of $X_k$ pass through $y$. However, on one of these two components (the one with odd index), both $f$ and $g$ are constant, since they are pullbacks of functions on $X_{k-1}$. Since $fg = 0$ everywhere, either $f$ or $g$ (say, $f$) vanishes on the other component. This implies that $f$ vanishes on both components, as required.

6. Noncomplete completion

Let $R$ be a ring and let $m$ be a maximal ideal. Consider the completion

$$R^\wedge = \lim_{\rightarrow} R/m^n.$$

Note that $R^\wedge$ is a local ring with maximal ideal $m' = \text{Ker}(R^\wedge \to R/m)$. Namely, if $x = (x_n) \in R^\wedge$ is not in $m'$, then $y = (x_n^{-1}) \in R^\wedge$ satisfies $xy = 1$, whence $R^\wedge$ is local by Algebra, Lemma \ref{lem-17-2}. Now it is always true that $R^\wedge$ complete in its limit topology (see the discussion in More on Algebra, Section \ref{sec-27}). But beyond that, we have the following questions:
EXAMPLES

(1) Is it true that $mR^{\wedge} = m'$?
(2) Is $R^{\wedge}$ viewed as an $R^{\wedge}$-module $m'$-adically complete?
(3) Is $R^{\wedge}$ viewed as an $R$-module $m$-adically complete?

It turns out that of these questions all have a negative answer. The example below was taken from an unpublished note of Bart de Smit and Hendrik Lenstra. See also [Bou61, Exercise III.2.12] and [Yek11, Example 1.8]

Let $k$ be a field, $R = k[x_1, x_2, x_3, \ldots]$, and $m = (x_1, x_2, x_3, \ldots)$. We will think of an element $f$ of $R^{\wedge}$ as a (possibly) infinite sum

$$f = \sum a_l x^l$$

(using multi-index notation) such that for each $d \geq 0$ there are only finitely many nonzero $a_l$ for $|l| = d$. The maximal ideal $m' \subset R^{\wedge}$ is the collection of $f$ with zero constant term. In particular, the element

$$f = x_1 + x_2^2 + x_3^3 + \ldots$$

is in $m'$ but not in $mR^{\wedge}$ which shows that (1) is false in this example. Note that we do have $mR^{\wedge} \subset m'$. Hence, $R^{\wedge}$ is not $m$-adically complete as an $R$-module, then it is also not $m'$-adically complete. To show that $R^{\wedge}$ is not $m$-adically complete (as an $R$-module) it suffices to show that $K_2 = \text{Ker}(R^{\wedge} \to R/m^2)$ is not equal to $m^2R^{\wedge}$, see Algebra, Lemma 94.6. Note that an element of $m^2R^{\wedge} \subset (m')^2$ can be written as a finite sum

$$(6.0.1) \sum_{i=1, \ldots, t} f_i g_i$$

with $f_i, g_i \in R^{\wedge}$ having vanishing constant terms. To get an example we are going to choose an $z \in K_2$ of the form

$$z = z_1 + z_2 + z_3 + \ldots$$

with the following properties

(1) there exist sequences $1 < d_1 < d_2 < d_3 < \ldots$ and $0 < n_1 < n_2 < n_3 < \ldots$ such that $z_i \in k[[x_{n_1}, x_{n_1+1}, \ldots, x_{n_{i+1}-1}]]$ homogeneous of degree $d_i$, and

(2) in the ring $k[[x_{n_1}, x_{n_1+1}, \ldots, x_{n_{i+1}-1}]]$ the element $z_i$ cannot be written as a sum (6.0.1) with $t \leq i$.

Clearly this implies that $z$ is not in $(m')^2$ because the image of the relation (6.0.1) in the ring $k[[x_{n_1}, x_{n_1+1}, \ldots, x_{n_{i+1}-1}]]$ for $i$ large enough would produce a contradiction. Hence it suffices to prove that for all $t > 0$ there exists a $d > 0$ and an integer $n$ such that we can find an homogeneous element $z \in k[x_{1, \ldots, x_n}]$ of degree $d$ which cannot be written as a sum (6.0.1) for the given $t$ in $k[[x_{1, \ldots, x_n}]]$. Take $n > 2t$ and any $d > 1$ prime to the characteristic of $p$ and set $z = \sum_{i=1, \ldots, n} x_i^d$.

Then the vanishing locus of the ideal

$$\left( \frac{\partial z}{\partial x_1}, \ldots, \frac{\partial z}{\partial x_n} \right) = (dx_1^{d-1}, \ldots, dx_n^{d-1})$$

consists of one point. On the other hand,

$$\frac{\partial (\sum_{i=1, \ldots, t} f_i g_i)}{\partial x_j} \in (f_1, \ldots, f_t, g_1, \ldots, g_t)$$

by the Leibniz rule and hence the vanishing locus of these derivatives contains at least

$$V(f_1, \ldots, f_t, g_1, \ldots, g_t) \subset \text{Spec}(k[[x_1, \ldots, x_n]])$$. 
Hence this is a contradiction as the dimension of \( V(f_1, \ldots, f_t, g_1, \ldots, g_t) \) is at least \( n - 2t \geq 1 \).

**Lemma 6.1.** There exists a local ring \( R \) and a maximal ideal \( \mathfrak{m} \) such that the completion \( R^\wedge \) of \( R \) with respect to \( \mathfrak{m} \) has the following properties

1. \( R^\wedge \) is local, but its maximal ideal is not equal to \( \mathfrak{m}R^\wedge \),
2. \( R^\wedge \) is not a complete local ring, and
3. \( R^\wedge \) is not \( \mathfrak{m} \)-adically complete as an \( R \)-module.

**Proof.** This follows from the discussion above as (with \( R = k[x_1, x_2, x_3, \ldots] \)) the completion of the localization \( R_\mathfrak{m} \) is equal to the completion of \( R \).

### 7. Noncomplete quotient

Let \( k \) be a field. Let

\[
R = k[t, z_1, z_2, z_3, \ldots, w_1, w_2, w_3, \ldots, x]/(z_1t - x^i w_i, z_i w_j)
\]

Note that in particular \( z_i z_j t = 0 \) in this ring. Any element \( f \) of \( R \) can be uniquely written as a finite sum

\[
f = \sum_{i=0}^{d} f_i x^i
\]

where each \( f_i \in k[t, z_i, w_j] \) has no terms involving the products \( z_i t \) or \( z_i w_j \). Moreover, if \( f \) is written in this way, then \( f \in \langle x^n \rangle \) if and only if \( f_i = 0 \) for \( i < n \). So \( x \) is a nonzero divisor and \( \bigcap \langle x^n \rangle = 0 \). Let \( R^\wedge \) be the completion of \( R \) with respect to the ideal \( \langle x \rangle \). Note that \( R^\wedge \) is \( \langle x \rangle \)-adically complete, see Algebra, Lemma \( \text{[94.7]} \). By the above we see that an element of \( R^\wedge \) can be uniquely written as an infinite sum

\[
f = \sum_{i=0}^{\infty} f_i x^i
\]

where each \( f_i \in k[t, z_i, w_j] \) has no terms involving the products \( z_i t \) or \( z_i w_j \). Consider the element

\[
f = \sum_{i=1}^{\infty} x^i w_i = xw_1 + x^2 w_2 + x^3 w_3 + \ldots
\]

i.e., we have \( f_n = w_n \). Note that \( f \in \langle t, \langle x^n \rangle \rangle \) for every \( n \) because \( x^m w_m \in \langle t \rangle \) for all \( m \). We claim that \( f \not\in \langle t \rangle \). To prove this assume that \( t q = f \) where \( q = \sum g_l x^l \) in canonical form as above. Since \( t z_i z_j = 0 \) we may as well assume that none of the \( g_l \) have terms involving the products \( z_i z_j \). Examining the process to get \( t q \) in canonical form we see the following: Given any term \( cm \) of \( g_l \) where \( c \in k \) and \( m \) is a monomial in \( t, z_i, w_j \) and we make the following replacement

1. if the monomial \( m \) does not involve any \( z_i \), then \( c t m \) is a term of \( f_i \), and
2. if the monomial \( m \) does involve a \( z_i \) then it is equal to \( m = z_i \) and we see that \( c w_i \) is term of \( f_{t+i} \).

Since \( g_0 \) is a polynomial only finitely many of the variables \( z_i \) occur in it. Pick \( n \) such that \( z_n \) does not occur in \( g_0 \). Then the rules above show that \( w_n \) does not occur in \( f_n \) which is a contradiction. It follows that \( R^\wedge / \langle t \rangle \) is not complete, see Algebra, Lemma \( \text{[94.15]} \).

**Lemma 7.1.** There exists a ring \( R \) complete with respect to a principal ideal \( I \) and a principal ideal \( J \) such that \( R/J \) is not \( I \)-adically complete.

**Proof.** See discussion above.
8. Completion is not exact

A quick example is the following. Suppose that $R = k[t]$. Let $P = K = \bigoplus_{n \in \mathbb{N}} R$ and $M = \bigoplus_{n \in \mathbb{N}} R/(t^n)$. Then there is a short exact sequence $0 \to K \to P \to M \to 0$ where the first map is given by multiplication by $t^n$ on the $n$th summand. We claim that $0 \to K^\wedge \to P^\wedge \to M^\wedge \to 0$ is not exact in the middle. Namely, $\xi = (t^2, t^3, t^4, \ldots) \in P^\wedge$ maps to zero in $M^\wedge$ but is not in the image of $K^\wedge \to P^\wedge$, because it would be the image of $(t, t, t, \ldots)$ which is not an element of $K^\wedge$.

A “smaller” example is the following. In the situation of Lemma 7.1 the short exact sequence $0 \to J \to R \to R/J \to 0$ does not remain exact after completion. Namely, if $f \in J$ is a generator, then $f : R \to J$ is surjective, hence $R \to J^\wedge$ is surjective, hence the image of $J^\wedge \to R$ is $(f) = J$ but the fact that $R/J$ is noncomplete means that the kernel of the surjection $R \to (R/J)^\wedge$ is strictly bigger than $J$, see Algebra, Lemmas 94.1 and 94.15. By the same token the sequence $R \to R \to R/(f) \to 0$ does not remain exact on completion.

**Lemma 8.1.** Completion is not an exact functor in general; it is not even right exact in general. This holds even when $I$ is finitely generated on the category of finitely presented modules.

**Proof.** See discussion above. □

9. The category of complete modules is not abelian

Let $R$ be a ring and let $I \subset R$ be a finitely generated ideal. Consider the category $\mathcal{A}$ of $I$-adically complete $R$-modules, see Algebra, Definition 94.5. Let $\varphi : M \to N$ be a morphism of $\mathcal{A}$. The cokernel of $\varphi$ in $\mathcal{A}$ is the completion (Coker($\varphi$))$^\wedge$ of the usual cokernel (as $I$ is finitely generated this completion is complete, see Algebra, Lemma 94.7). Let $K = \text{Ker}(\varphi)$. We claim that $K$ is complete and hence is the kernel of $\varphi$ in $\mathcal{A}$. Namely, let $K^\wedge$ be the completion. As $M$ is complete we obtain a factorization

$$K \to K^\wedge \to M \xrightarrow{\varphi} N$$

Since $\varphi$ is continuous for the $I$-adic topology, $K \to K^\wedge$ has dense image, and $K = \text{Ker}(\varphi)$ we conclude that $K^\wedge$ maps into $K$. Thus $K^\wedge = K \oplus C$ and $K$ is a direct summand of a complete module, hence complete.

We will give an example that shows that $\text{Im} \neq \text{Coim}$ in general. We take $R = \mathbb{Z}_p = \lim_{\to} \mathbb{Z}/p^n\mathbb{Z}$ to be the ring of $p$-adic integers and we take $I = (p)$. Consider the map

$$\text{diag}(1, p, p^2, \ldots) : \left( \bigoplus_{n \geq 1} \mathbb{Z}_p \right)^\wedge \rightarrow \prod_{n \geq 1} \mathbb{Z}_p$$

where the left hand side is the $p$-adic completion of the direct sum. Hence an element of the left hand side is a vector $(x_1, x_2, x_3, \ldots)$ with $x_i \in \mathbb{Z}_p$ with $p$-adic valuation $v_p(x_i) \to \infty$ as $i \to \infty$. This maps to $(x_1, px_2, p^2 x_3, \ldots)$. Hence we see that $(1, p, p^2, \ldots)$ is in the closure of the image but not in the image. By our description of kernels and cokernels above it is clear that $\text{Im} \neq \text{Coim}$ for this map.

**Lemma 9.1.** Let $R$ be a ring and let $I \subset R$ be a finitely generated ideal. The category of $I$-adically complete $R$-modules has kernels and cokernels but is not abelian in general.

**Proof.** See above. □
10. The category of derived complete modules

Let $A$ be a ring and let $I$ be an ideal. Consider the category $\mathcal{C}$ of derived complete modules as defined in More on Algebra, Definition 67.4. By More on Algebra, Lemma 67.6 we see that $\mathcal{C}$ is abelian.

Let $T$ be a set and let $M_t, t \in T$ be a family of derived complete modules. We claim that in general $\bigoplus M_t$ is not a complete module. For a specific example, let $A = \mathbb{Z}_p$ and $I = (p)$ and $\bigoplus_{n \in \mathbb{N}} \mathbb{Z}_p$. The map from $\bigoplus_{n \in \mathbb{N}} \mathbb{Z}_p$ to its $p$-adic completion isn’t surjective. This means that $\bigoplus_{n \in \mathbb{N}} \mathbb{Z}_p$ cannot be derived complete as this would imply otherwise, see More on Algebra, Lemma 67.3.

Assume $I$ is finitely generated. Let $^\wedge : D(A) \to D(A)$ denote the derived completion functor, see More on Algebra, Lemma 67.9. We claim that

$$M = H^0((\bigoplus M_t)^\wedge) \in \text{Ob}(\mathcal{C})$$

is a direct sum of $M_t$ in the category $\mathcal{C}$. Note that for $E$ a derived complete object of $D(A)$ we have

$$\text{Hom}_{D(A)}((\bigoplus M_t)^\wedge, E) = \text{Hom}_{D(A)}(\bigoplus M_t, E) = \prod \text{Hom}_{D(A)}(M_t, E)$$

Note that the right hand side is zero if $H^i(E) = 0$ for $i < 1$. In particular, applying this with $E = \tau_{\geq 1}(\bigoplus M_t)^\wedge$ which is derived complete by More on Algebra, Lemma 67.6 we see that the canonical map $\bigoplus M_t \to \tau_{\geq 1}(\bigoplus M_t)^\wedge$ is zero, in other words, we have $H^i((\bigoplus M_t)^\wedge) = 0$ for $i \geq 1$. Then, for an object $N \in \mathcal{C}$ we see that

$$\text{Hom}_{\mathcal{C}}(M, N) = \text{Hom}_{D(A)}((\bigoplus M_t)^\wedge, N) = \prod \text{Hom}_{\mathcal{C}}(M_t, N) = \prod \text{Hom}_{A}(M_t, N)$$

as desired. This implies that $\mathcal{C}$ has all colimits, see Categories, Lemma 14.11. In fact, arguing similarly as above we see that given a system $M_t$ in $\mathcal{C}$ over a partially ordered set $T$ the colimit in $\mathcal{C}$ is equal to $H^0((\text{colim} M_t)^\wedge)$ where the inner colimit is the colimit in the category of $A$-modules.

However, we claim that filtered colimits are not exact in the category $\mathcal{C}$. Namely, suppose that $A = \mathbb{Z}_p$ and $I = (p)$. One has inclusions $f_n : \mathbb{Z}_p/p^n \mathbb{Z}_p \to \mathbb{Z}_p/p^{n+1} \mathbb{Z}_p$ of $p$-adically complete $A$-modules given by multiplication by $p^{n-1}$. There are commutative diagrams

$$\begin{array}{ccc}
\mathbb{Z}_p/p^n \mathbb{Z}_p & \xrightarrow{f_n} & \mathbb{Z}_p/p^{n+1} \mathbb{Z}_p \\
\downarrow 1 & & \downarrow p \\
\mathbb{Z}_p/p^{n+1} \mathbb{Z}_p & \xrightarrow{f_{n+1}} & \mathbb{Z}_p/p^{n+2} \mathbb{Z}_p
\end{array}$$

Now take the colimit of these inclusions in the category $\mathcal{C}$ derived to get $\mathbb{Z}_p/p \mathbb{Z}_p \to \mathbb{Z}_p/p^n \mathbb{Z}_p \to 0$. Namely, the colimit in $\text{Mod}_A$ of the system on the right is $\mathbb{Q}_p/\mathbb{Z}_p$. The reader can directly compute that $(\mathbb{Q}_p/\mathbb{Z}_p)^\wedge = \mathbb{Z}_p[1]$ in $D(A)$. Thus $H^0 = 0$ which proves our claim.

**Lemma 10.1.** Let $A$ be a ring and let $I \subseteq A$ be an ideal. The category $\mathcal{C}$ of derived complete modules is abelian and the inclusion functor $F : \mathcal{C} \to \text{Mod}_A$ is exact and commutes with arbitrary limits. If $I$ is finitely generated, then $\mathcal{C}$ has arbitrary
EXAMPLES

direct sums and colimits, but \( F \) does not commute with these in general. Finally, filtered colimits are not exact in \( \mathcal{C} \) in general, hence \( \mathcal{C} \) is not a Grothendieck abelian category.

Proof. See discussion above.

11. Nonflat completions

In this section we give some examples of completions which are not exact.

Lemma 11.1. Let \( R \) be a ring. Let \( M \) be an \( R \)-module which is countable. Then \( M \) is a finite \( R \)-module if and only if \( M \otimes_R R^N \rightarrow M^N \) is surjective.

Proof. If \( M \) is a finite module, then the map is surjective by Algebra, Proposition 87.2. Conversely, assume the map is surjective. Let \( m_1, m_2, m_3, \ldots \) be an enumeration of the elements of \( M \). Let \( \sum_{j=1}^m x_j \otimes a_j \) be an element of the tensor product mapping to the element \((m_n) \in M^N\). Then we see that \( x_1, \ldots, x_m \) generate \( M \) over \( R \) as in the proof of Algebra, Proposition 87.2.

Lemma 11.2. Let \( R \) be a countable ring. Let \( M \) be a countable \( R \)-module. Then \( M \) is finitely presented if and only if the canonical map \( M \otimes_R R^N \rightarrow M^N \) is an isomorphism.

Proof. If \( M \) is a finitely presented module, then the map is an isomorphism by Algebra, Proposition 87.3. Conversely, assume the map is an isomorphism. By Lemma 11.1 the module \( M \) is finite. Choose a surjection \( R^{\oplus m} \rightarrow M \) with kernel \( K \). Then \( K \) is countable as a submodule of \( R^{\oplus m} \). Arguing as in the proof of Algebra, Proposition 87.3 we see that \( K \otimes R R^N \rightarrow K^N \) is surjective. Hence we conclude that \( K \) is a finite \( R \)-module by Lemma 11.1. Thus \( M \) is finitely presented.

Lemma 11.3. Let \( R \) be a countable ring. Then \( R \) is coherent if and only if \( R^N \) is a flat \( R \)-module.

Proof. If \( R \) is coherent, then \( R^N \) is a flat module by Algebra, Proposition 88.5. Assume \( R^N \) is flat. Let \( I \subset R \) be a finitely generated ideal. To prove the lemma we show that \( I \) is finitely presented as an \( R \)-module. Namely, the map \( I \otimes_R R^N \rightarrow R^N \) is injective as \( R^N \) is flat and its image is \( I^N \) by Lemma 11.1. Thus we conclude by Lemma 11.2.

Let \( R \) be a countable ring. Observe that \( R[[x]] \) is isomorphic to \( R^N \) as an \( R \)-module. By Lemma 11.3 we see that \( R \rightarrow R[[x]] \) is flat if and only if \( R \) is coherent. There are plenty of noncoherent countable rings, for example

\[
R = k[y, z, a_1, a_2, b_1, b_2, a_3, b_3, \ldots]/(a_1y + b_1z, a_2y + b_2z, a_3y + b_3z, \ldots)
\]

where \( k \) is a countable field. This ring is not coherent because the ideal \((y, z)\) of \( R \) is not a finitely presented \( R \)-module. Note that \( R[[x]] \) is the completion of \( R[x] \) by the principal ideal \((x)\).

Lemma 11.4. There exists a ring such that the completion \( R[[x]] \) of \( R[x] \) at \((x)\) is not flat over \( R \) and a fortiori not flat over \( R[x] \).

Proof. See discussion above.
Next, we will construct an example where the completion of a localization is nonflat. To do this consider the ring

\[ R = k[y, z, a_1, a_2, a_3, \ldots]/(ya_i, a_ia_j) \]

Denote \( f \in R \) the residue class of \( z \). We claim the ring map

\[ R[[x]] \rightarrow R_f[[x]] \]

isn’t flat. Let \( I \) be the kernel of \( y : R[[x]] \rightarrow R[[x]] \). A typical element \( g \) of \( I \) looks like \( g = \sum g_{n,m}a_mx^n \) where \( g_{n,m} \in k[z] \) and for a given \( n \) only a finite number of nonzero \( g_{n,m} \). Let \( J \) be the kernel of \( y : R_f[[x]] \rightarrow R_f[[x]] \). We claim that \( J \neq IR_f[[x]] \). Namely, if this were true then we would have

\[ \sum z^{-n}a_nx^n = \sum_{i=1, \ldots, m}^{} h_ig_i \]

for some \( m \geq 1 \), \( g_i \in I \), and \( h_i \in R_f[[x]] \). Say \( h_i = \bar{h}_i \mod (y, a_1, a_2, a_3, \ldots) \) with \( \bar{h}_i \in k[z, 1/z][[x]] \). Looking at the coefficient of \( a_n \) and using the description of the elements \( g_i \) above we would get

\[ z^{-n}x^n = \sum \bar{h}_ig_{i,n} \]

for some \( \bar{g}_{i,n} \in k[z][[x]] \). This would mean that all \( z^{-n}x^n \) are contained in the finite \( k[z][[x]] \)-module generated by the elements \( \bar{h}_i \). Since \( k[z][[x]] \) is Noetherian this implies that the \( R[z][[x]] \)-submodule of \( k[z, 1/z][[x]] \) generated by \( 1, z^{-1}x, z^{-2}x^2, \ldots \) is finite. By Algebra, Lemma 35.2 we would conclude that \( z^{-1}x \) is integral over \( k[z][[x]] \) which is absurd. On the other hand, if \( R_f[[x]] \) were flat, then we would get \( J = IR_f[[x]] \) by tensoring the exact sequence \( 0 \rightarrow I \rightarrow R[[x]] \xrightarrow{y} R[[x]] \) with \( R_f[[x]] \).

**Lemma 11.5.** There exists a ring \( A \) complete with respect to a principal ideal \( I \) and an element \( f \in A \) such that the \( I \)-adic completion \( A_f^I \) of \( A_f \) is not flat over \( A \).

**Proof.** Set \( A = R[[x]] \) and \( I = (x) \) and observe that \( R_f[[x]] \) is the completion of \( R[[x]]_f \).

12. Nonabelian category of quasi-coherent modules

In Sheaves on Stacks, Section 11 we defined the category of quasi-coherent modules on a category fibred in groupoids over \( Sch \). Although we show in Sheaves on Stacks, Section 14 that this category is abelian for algebraic stacks, in this section we show that this is not the case for formal algebraic spaces.

Namely, consider \( \mathbb{Z}_p \) viewed as topological ring using the \( p \)-adic topology. Let \( X = \text{Spf}(\mathbb{Z}_p) \), see Formal Spaces, Definition 5.9. Then \( X \) is a sheaf in sets on \( (Sch/\mathbb{Z})_{fppf} \) and gives rise to a stack in setoids \( \mathcal{X} \), see Stacks, Lemma 6.2 Thus the discussion of Sheaves on Stacks, Section 14 applies.

Let \( \mathcal{F} \) be a quasi-coherent module on \( \mathcal{X} \). Since \( X = \text{colim} \text{Spec}(\mathbb{Z}/p^n\mathbb{Z}) \) it is clear from Sheaves on Stacks, Lemma 11.5 that \( \mathcal{F} \) is given by a sequence \( (\mathcal{F}_n) \) where

(1) \( \mathcal{F}_n \) is a quasi-coherent module on \( \text{Spec}(\mathbb{Z}/p^n\mathbb{Z}) \), and

(2) the transition maps give isomorphisms \( \mathcal{F}_n = \mathcal{F}_{n+1}/p^n\mathcal{F}_{n+1} \).
Converting into modules we see that \( F \) corresponds to a system \( (M_i) \) where each \( M_i \) is an abelian group annihilated by \( p^i \) and the transition maps induce isomorphisms \( M_i = M_{i+1}/p^iM_{i+1} \). In this situation the module \( M = \lim M_i \) is a \( p \)-adically complete module and \( M_i = M/p^iM \), see Algebra, Lemma [95.1]. We conclude that the category of quasi-coherent modules on \( X \) is equivalent to the category of \( p \)-adically complete abelian groups. This category is not abelian, see Section [9].

**Lemma 12.1.** The category of quasi-coherent modules on a formal algebraic space \( X \) is not abelian in general, even if \( X \) is a Noetherian affine formal algebraic space.

**Proof.** See discussion above. \( \square \)

13. Regular sequences and base change

We are going to construct a ring \( R \) with a regular sequence \( (x, y, z) \) such that there exists a nonzero element \( \delta \in R/zR \) with \( x\delta = y\delta = 0 \).

To construct our example we first construct a peculiar module \( E \) over the ring \( k[x, y, z] \) where \( k \) is any field. Namely, \( E \) will be a push-out as in the following diagram

\[
\begin{array}{ccc}
xk[x,y,z,y^{-1}] & \xrightarrow{k[x,y,z,x^{-1},y^{-1}]} & k[x,y,z,x^{-1},y^{-1}] \\
\downarrow z/x & & \downarrow yk[x,y,z,x^{-1}]
\end{array}
\]

where the rows are short exact sequences (we dropped the outer zeros due to type-setting problems). Another way to describe \( E \) is as

\[
E = \{(f, g) \mid f \in k[x, y, z, x^{-1}, y^{-1}], g \in k[x, y, z, y^{-1}] \}/\sim
\]

where \( (f, g) \sim (f', g') \) if and only if there exists a \( h \in k[x, y, z, y^{-1}] \) such that

\[
f = f' + xh \mod yk[x, y, z, x^{-1}], \quad g = g' - zh \mod yzk[x, y, z]
\]

We claim: (a) \( x : E \to E \) is injective, (b) \( y : E/xE \to E/xE \) is injective, (c) \( E/(x, y)E = 0 \), (d) there exists a nonzero element \( \delta \in E/zE \) such that \( x\delta = y\delta = 0 \).

To prove (a) suppose that \( (f, g) \) is a pair that gives rise to an element of \( E \) and that \( (xf, xg) \sim 0 \). Then there exists a \( h \in k[x, y, z, y^{-1}] \) such that \( xf + xh \in yk[x, y, z, x^{-1}] \) and \( xg - zh \in yzk[x, y, z] \). We may assume that \( h = \sum a_{i,j,k}x^iy^jz^k \) is a sum of monomials where only \( j \leq 0 \) occurs. Then \( xg - zh \in yzk[x, y, z] \) implies that only \( i > 0 \) occurs, i.e., \( h = xh' \) for some \( h' \in k[x, y, z, y^{-1}] \). Then \( (f, g) \sim (f + xh', g - zh') \) and we see that we may assume that \( g = 0 \) and \( h = 0 \). In this case \( xf \in yk[x, y, z, x^{-1}] \) and we see that \( (f, g) \sim 0 \). Thus \( x : E \to E \) is injective.
Since multiplication by $x$ is an isomorphism on \[ \frac{k[x,y,z,x^{-1},y^{-1}]}{y[k[x,y,z,x^{-1}]} \] we see that $E/xE$ is isomorphic to \[ \frac{yzk[x,y,z] + xk[x,y,z,y^{-1}]}{xk[x,y,z,y^{-1}] + zk[x,y,z,y^{-1}]} = \frac{k[x,y,z,y^{-1}]}{zk[x,y,z,y^{-1}]} \] and hence multiplication by $y$ is an isomorphism on $E/xE$. This clearly implies (b) and (c).

Let $e \in E$ be the equivalence class of $(1,0)$. Suppose that $e \in zE$. Then there exist $f \in k[x,y,z,x^{-1},y^{-1}]$, $g \in k[x,y,z,y^{-1}]$, and $h \in k[x,y,z,y^{-1}]$ such that
\[ 1 + zf + xh \in yk[x,y,z,x^{-1}], \quad 0 + zg - zh \in yzk[x,y,z]. \]
This is impossible: the monomial 1 cannot occur in $zf$, nor in $xh$. On the other hand, we have $ye = 0$ and $xe = (x,0) \sim (0,-z) = z(0,-1)$. Hence setting $\delta$ equal to the congruence class of $e$ in $E/zE$ we obtain (d).

**Lemma 13.1.** There exists a local ring $R$ and a regular sequence $x,y,z$ (in the maximal ideal) such that there exists a nonzero element $\delta \in R/zR$ with $x\delta = y\delta = 0$.

**Proof.** Let $R = k[x,y,z] \oplus E$ where $E$ is the module above considered as a square zero ideal. Then it is clear that $x,y,z$ is a regular sequence in $R$, and that the element $\delta \in E/zE \subset R/zR$ gives an element with the desired properties. To get a local example we may localize $R$ at the maximal ideal $m = (x,y,z,E)$. The sequence $x,y,z$ remains a regular sequence (as localization is exact), and the element $\delta$ remains nonzero as it is supported at $m$.

**Lemma 13.2.** There exists a local homomorphism of local rings $A \to B$ and a regular sequence $x,y$ in the maximal ideal of $B$ such that $B/(x,y)$ is flat over $A$, but such that the images $\overline{x}, \overline{y}$ of $x,y$ in $B/m_A B$ do not form a regular sequence, nor even a Koszul-regular sequence.

**Proof.** Set $A = k[z]_{(z)}$ and let $B = (k[x,y,z] \oplus E)_{(x,y,z,E)}$. Since $x,y,z$ is a regular sequence in $B$, see proof of Lemma 13.1 we see that $x,y$ is a regular sequence in $B$ and that $B/(x,y)$ is a torsion free $A$-module, hence flat. On the other hand, there exists a nonzero element $\delta \in B/m_A B = B/zB$ which is annihilated by $\overline{x}, \overline{y}$. Hence $H_2(K_*(B/m_A B, \overline{x}, \overline{y})) \neq 0$. Thus $\overline{x}, \overline{y}$ is not Koszul-regular, in particular it is not a regular sequence, see More on Algebra, Lemma 22.2.

### 14. A Noetherian ring of infinite dimension

A Noetherian local ring has finite dimension as we saw in Algebra, Proposition 59.8. But there exist Noetherian rings of infinite dimension. See [Nag02 Appendix, Example 1].

Namely, let $k$ be a field, and consider the ring
\[ R = k[x_1, x_2, x_3, \ldots]. \]
Let $\mathfrak{p}_i = (x_{2^{-1}}, x_{2^{-1}+1}, \ldots, x_{2^{-1}})$ for $i = 1, 2, \ldots$ which are prime ideals of $R$. Let $S$ be the multiplicative subset
\[ S = \bigcap_{i \geq 1} (R \setminus \mathfrak{p}_i). \]
Consider the ring $A = S^{-1}R$. We claim that

1. The maximal ideals of the ring $A$ are the ideals $\mathfrak{m}_i = \mathfrak{p}_i A$.
(2) We have $A_{m_i} = R_p$, which is a Noetherian local ring of dimension $2^i$.

(3) The ring $A$ is Noetherian.

Hence it is clear that this is the example we are looking for. Details omitted.

15. Local rings with nonreduced completion

In Algebra, Example 116.4 we gave an example of a characteristic $p$ Noetherian local domain $R$ of dimension 1 whose completion is nonreduced. In this section we present the example of [FR70, Proposition 3.1] which gives a similar ring in characteristic zero.

Let $C\{x\}$ be the ring of convergent power series over the field $C$ of complex numbers. The ring of all power series $C[[x]]$ is its completion. Let $K = C\{x\}[1/x] = f.f.(B)$ be the field of convergent Laurent series. The $K$-module $\Omega_{K/C}$ of algebraic differentials of $K$ over $C$ is an infinite dimensional $K$-vector space (proof omitted). We may choose $f_n \in xC\{x\}$, $n \geq 1$ such that $dx, df_1, df_2, \ldots$ are part of a basis of $\Omega_{K/C}$. Thus we can find a $C$-derivation

$$D : C\{x\} \to C((x))$$

such that $D(x) = 0$ and $D(f_i) = x^{-n}$. Let

$$A = \{f \in C\{x\} \mid D(f) \in C[[x]]\}$$

We claim that

1. $C\{x\}$ is integral over $A$,
2. $A$ is a local domain,
3. $\dim(A) = 1$,
4. the maximal ideal of $A$ is generated by $x$ and $xf_1$,
5. $A$ is Noetherian, and
6. the completion of $A$ is equal to the ring of dual numbers over $C[[x]]$.

Since the dual numbers are nonreduced the ring $A$ gives the example.

Note that if $0 \neq f \in xC\{x\}$ then we may write $D(f) = h/f^n$ for some $n \geq 0$ and $h \in C[[x]]$. Hence $D(f^{n+1}/(n + 1)) \in C[[x]]$ and $D(f^{n+2}/(n + 2)) \in C[[x]]$. Thus we see $f^{n+1}, f^{n+2} \in A!$ In particular we see (1) holds. We also conclude that the fraction field of $A$ is equal to the fraction field of $C\{x\}$. It also follows immediately that $A \cap xC\{x\}$ is the set of nonunits of $A$, hence $A$ is a local domain of dimension 1. If we can show (4) then it will follow that $A$ is Noetherian (proof omitted). Suppose that $f \in A \cap xC\{x\}$. Write $D(f) = h$, $h \in C[[x]]$. Write $h = c + xh'$ with $c \in C$, $h' \in C[[x]]$. Then $D(f - cxf_1) = c + xh' - c = xh'$. On the other hand $f - cxf_1 = xg$ with $g \in C\{x\}$, but by the computation above we have $D(g) = h' \in C[[x]]$ and hence $g \in A$. Thus $f = cxf_1 + xg \in (x, xf_1)$ as desired.

Finally, why is the completion of $A$ nonreduced? Denote $\hat{A}$ the completion of $A$. Of course this maps surjectively to the completion $C[[x]]$ of $C\{x\}$ because $x \in A$. Denote this map $\psi : \hat{A} \to C[[x]]$. Above we saw that $m_A = (x, xf_1)$ and hence $D(m_A^\prime) \subset (x^{n-1})$ by an easy computation. Thus $D : A \to C[[x]]$ is continuous and gives rise to a continuous derivation $\hat{D} : \hat{A} \to C[[x]]$ over $\psi$. Hence we get a ring map

$$\psi + \epsilon \hat{D} : \hat{A} \to C[[x]][\epsilon].$$

Since $\hat{A}$ is a one dimensional Noetherian complete local ring, if we can show this arrow is surjective then it will follow that $\hat{A}$ is nonreduced. Actually the map is an
isomorphism but we omit the verification of this. The subring $C[x](x) \subset A$ gives rise to a map $i : C[[x]] \to A$ on completions such that $i \circ \psi = \text{id}$ and such that $D \circ i = 0$ (as $D(x) = 0$ by construction). Consider the elements $x^n f_n \in A$. We have
$$(\psi + \epsilon D)(x^n f_n) = x^n f_n + \epsilon$$
for all $n \geq 1$. Surjectivity easily follows from these remarks.

16. A non catenary Noetherian local ring

Even though there is a successful dimension theory of Noetherian local rings there are non-catenary Noetherian local rings. An example may be found in [Nag62, Appendix, Example 2]. In fact, we will present this example in the simplest case. Namely, we will construct a local Noetherian domain $A$ of dimension 2 which is not universally catenary. (Note that $A$ is automatically catenary, see Exercises, Exercise [12.2). The existence of a Noetherian local ring which is not universally catenary implies the existence of a Noetherian local ring which is not catenary – and we spell this out at the end of this section in the particular example at hand.

Let $k$ be a field, and consider the formal power series ring $k[[x]]$ in one variable over $k$. Let
$$z = \sum_{i=1}^{\infty} a_i x^i$$
be a formal power series. We assume $z$ as an element of the Laurent series field $k((x)) = f.f.(k[[x]])$ is transcendental over $k(x)$. Put
$$z_j = x^{-j}(z - \sum_{i=1, \ldots, j-1} a_i x^i) = \sum_{i=j}^{\infty} a_i x^{i-j} \in k[[x]].$$
Note that $z = z_1$. Let $R$ be the subring of $k[[x]]$ generated by $x$, $z$ and all of the $z_j$, in other words
$$R = k[x, z_1, z_2, z_3, \ldots] \subset k[[x]].$$
Consider the ideals $m = (x)$ and $n = (x-1, z_1, z_2, \ldots)$ of $R$.

We have $x(z_{j+1} + a_j) = z_j$. Hence $R/m = k$ and $m$ is a maximal ideal. Moreover, any element of $R$ not in $m$ maps to a unit in $k[[x]]$ and hence $R_m \subset k[[x]]$. In fact it is easy to deduce that $R_m$ is a discrete valuation ring and residue field $k$.

We claim that
$$R/(x - 1) = k[x, z_1, z_2, z_3, \ldots]/(x - 1) \cong k[z].$$
Namely, the relation above implies that $(x - 1)(z_{j+1} + a_j) = -z_{j+1} - a_j + z_j$, and hence we may express the class of $z_{j+1}$ in terms of $z_j$ in the quotient $R/(x - 1)$. Since the fraction field of $R$ has transcendence degree 2 over $k$ by construction we see that $z$ is transcendental over $k$ in $R/(x - 1)$, whence the desired isomorphism. Hence $n = (x - 1, z)$ and is a maximal ideal. In fact the map
$$k[x, x^{-1}, z]_{(x-1, z)} \longrightarrow R_n$$
is an isomorphism (since $x^{-1}$ is invertible in $R_n$ and since $z_{j+1} = x^{-1}z_j - a_j = \ldots = f_j(x, x^{-1}, z)$). This shows that $R_n$ is a regular local ring of dimension 2 and residue field $k$.

Let $S$ be the multiplicative subset
$$S = (R \setminus m) \cap (R \setminus n) = R \setminus (m \cup n)$$
and set $B = S^{-1}R$. We claim that

1. The ring $B$ is a $k$-algebra.
2. The maximal ideals of the ring $B$ are the two ideals $\mathfrak{m}B$ and $\mathfrak{n}B$.
3. The residue fields at these maximal ideals is $k$.
4. We have $B_{\mathfrak{m}B} = R_{\mathfrak{m}}$ and $B_{\mathfrak{n}B} = R_{\mathfrak{n}}$ which are Noetherian regular local rings of dimensions 1 and 2.
5. The ring $B$ is Noetherian.

We omit the details of the verifications.

Whenever given a $k$-algebra $B$ with the properties listed above we get an example as follows. Take $A = k + \text{rad}(B) \subset B$, in our case $\text{rad}(B) = mB + nB$. It is easy to see that $B$ is finite over $A$ and hence $A$ is Noetherian by Eakin’s theorem (see [Eak68], or [Nag62, Appendix A1], or insert future reference here). Also $A$ is a local domain with the same fraction field as $B$ and residue field $k$. Since the dimension of $B$ is 2 we see that $A$ has dimension 2 as well, by Algebra, Lemma 109.4.

If $A$ were universally catenary then the dimension formula, Algebra, Lemma 110.1 would give $\text{dim}(B_{\mathfrak{m}B}) = 2$ contradiction.

Note that $B$ is generated by one element over $A$. Hence $B = A[x]/\mathfrak{p}$ for some prime $\mathfrak{p}$ of $A[x]$. Let $\mathfrak{m}' \subset A[x]$ be the maximal ideal corresponding to $mB$. Then on the one hand $\text{dim}(A[x]_{\mathfrak{m}'}) = 3$ and on the other hand $(0) \subset \mathfrak{p}A[x]_{\mathfrak{m}'} \subset \mathfrak{m}'A[x]_{\mathfrak{m}'}$

is a maximal chain of primes. Hence $A[x]_{\mathfrak{m}'}$ is an example of a non catenary Noetherian local ring.

**17. Existence of bad local Noetherian rings**

Let $(A, \mathfrak{m}, \kappa)$ be a Noetherian complete local ring. In [Lec86a] it was shown that $A$ is the completion of a Noetherian local domain if $\text{depth}(A) \geq 1$ and $A$ contains either $\mathbb{Q}$, or $\mathbb{Z}$, or $\mathbb{F}_p$ as a subring. This produces many examples of Noetherian local domains with “bizarre” properties.

Applying this for example to $A = \mathbb{C}[[x, y]]/(y^2)$ we find a Noetherian local domain whose completion is nonreduced. Please compare with Section 15.

In [LLPY01] conditions were found that characterize when $A$ is the completion of a reduced local Noetherian ring.

In [Hei93] it was shown that $A$ is the completion of a local Noetherian UFD $R$ if $\text{depth}(A) \geq 2$ and $A$ contains either $\mathbb{Q}$, or $\mathbb{Z}$, or $\mathbb{F}_p$ as a subring. In particular $R$ is normal (Algebra, Lemma 117.8) hence the henselization of $R$ is a normal domain too (More on Algebra, Lemma 35.6). Thus $A$ as above is the completion of a henselian Noetherian local normal domain (because the completion of $R$ and its henselization agree, see More on Algebra, Lemma 35.3).

Apply this to find a Noetherian local UFD $R$ such that $R^\wedge \cong \mathbb{C}[[x, y, z, w]]/(wx, wy)$. Note that $\text{Spec}(R^\wedge)$ is the union of a regular 2-dimensional and a regular 3-dimensional component. The ring $R$ cannot be universally catenary: Let

$$X \longrightarrow \text{Spec}(R)$$

be the blowing up of the maximal ideal. Then $X$ is an integral scheme. There is a closed point $x \in X$ such that $\text{dim}(\mathcal{O}_{X,x}) = 2$, namely, on the level of the complete
EXAMPLES

local ring we pick $x$ to lie on the strict transform of the 2-dimensional component and not on the strict transform of the 3-dimensional component. By Morphisms, Lemma [31.1] we see that $R$ is not universally catenary. Please compare with Section 16.

The ring above is catenary (being a 3-dimensional local Noetherian UFD). However, in [Ogo80] the author constructs a normal local Noetherian domain $R$ with $R^\wedge \cong \mathbb{C}[x,y,z,w]/(wx, wy)$ such that $R$ is not catenary. See also [Hei82] and [Lec86b].

In [Hei94] it was shown that $A$ is the completion of a local Noetherian ring $R$ with an isolated singularity provided $A$ contains either $\mathbb{Q}$, or $\mathbb{Z}$, or $\mathbb{F}_p$ as a subring. Here we say a Noetherian local ring $R$ has an isolated singularity if $R_p$ is a regular local ring for all nonmaximal primes $p \subset R$.

As an aside, in [Loe03] it was shown that $A$ is the completion of an excellent Noetherian local domain if $A$ is reduced, equidimensional, and no integer in $A$ is a zero divisor. However, this doesn’t lead to “bad” Noetherian local rings as we obtain excellent ones!

18. Non-quasi-affine variety with quasi-affine normalization

The existence of an example of this kind is mentioned in [DG67, II Remark 6.6.13]. They refer to the fifth volume of EGA for such an example, but the fifth volume did not appear.

Let $k$ be a field. Let $Y = \mathbb{A}^2_k \setminus \{(0,0)\}$. We are going to construct a finite surjective birational morphism $\pi : Y \to X$ with $X$ a variety over $k$ such that $X$ is not quasi-affine. Namely, consider the following curves in $Y$:

- $C_1 : x = 0$
- $C_2 : y = 0$

Note that $C_1 \cap C_2 = \emptyset$. We choose the isomorphism $\varphi : C_1 \to C_2$, $(0, y) \mapsto (y^{-1}, 0)$. We claim there is a unique morphism $\pi : Y \to X$ as above such that

$$
\begin{array}{ccc}
C_1 & \xrightarrow{\text{id}} & Y \\
\varphi & \searrow & \swarrow \pi \\
 & X & 
\end{array}
$$

is a coequalizer diagram in the category of varieties (and even in the category of schemes). Accepting this for the moment let us show that such an $X$ cannot be quasi-affine. Namely, it is clear that we would get

$$
\Gamma(X, \mathcal{O}_X) = \{ f \in k[x,y] \mid f(0, y) = f(y^{-1}, 0) \} = k \oplus (xy) \subset k[x,y].
$$

In particular these functions do not separate the points $(1, 0)$ and $(-1, 0)$ whose images in $X$ (we will see below) are distinct (if the characteristic of $k$ is not 2).

To show that $X$ exists consider the Zariski open $D(x + y) \subset Y$ of $Y$. This is the spectrum of the ring $k[x, y, 1/(x + y)]$ and the curves $C_1, C_2$ are completely contained in $D(x + y)$. Moreover the morphism

$$
C_1 \coprod C_2 \to D(x + y) \cap Y = \text{Spec}(k[x, y, 1/(x + y)])
$$

is a closed immersion. It follows from More on Algebra, Lemma [4.1] that the ring

$$
A = \{ f \in k[x, y, 1/(x + y)] \mid f(0, y) = f(y^{-1}, 0) \}
$$
is of finite type over $k$. On the other hand we have the open $D(xy) \subset Y$ of $Y$ which is disjoint from the curves $C_1$ and $C_2$. It is the spectrum of the ring

$$B = k[x, y, 1/xy].$$

Note that we have $A_{xy} \cong B_{x+y}$ (since $A$ clearly contains the elements $xyP(x, y)$ any polynomial $P$ and the element $xy/(x + y)$). The scheme $X$ is obtained by gluing the affine schemes $\text{Spec}(A)$ and $\text{Spec}(B)$ using the isomorphism $A_{xy} \cong B_{x+y}$ and hence is clearly of finite type over $k$. To see that it is separated one has to show that the ring map $A \otimes_k B \to B_{x+y}$ is surjective. To see this use that $A \otimes_k B$ contains the element $xy/(x + y) \otimes 1/xy$ which maps to $1/(x + y)$. The morphism $X \to Y$ is given by the natural maps $D(x+y) \to \text{Spec}(A)$ and $D(xy) \to \text{Spec}(B)$.

Since these are both finite we deduce that $X \to Y$ is finite as desired. We omit the verification that $X$ is indeed the coequalizer of the displayed diagram above, however, see (insert future reference for pushouts in the category of schemes here).

Note that the morphism $\pi : Y \to X$ does map the points $(1,0)$ and $(-1,0)$ to distinct points in $X$ because the function $(x+y^3)/(x+y)^2 \in A$ has value $1/1$, resp. $-1/(-1)^2 = -1$ which are always distinct (unless the characteristic is 2 – please find your own points for characteristic 2). We summarize this discussion in the form of a lemma.

**Lemma 18.1.** Let $k$ be a field. There exists a variety $X$ whose normalization is quasi-affine but which is itself not quasi-affine.

**Proof.** See discussion above and (insert future reference on normalization here).

\[ \square \]

### 19. A locally closed subscheme which is not open in closed

This is a copy of Morphisms, Example 3.4. Here is an example of an immersion which is not a composition of an open immersion followed by a closed immersion.

Let $k$ be a field. Let $X = \text{Spec}(k[x_1, x_2, x_3, \ldots])$. Let $U = \bigcup_{n=1}^{\infty} D(x_n)$. Then $U \to X$ is an open immersion. Consider the ideals

$$I_n = (x_1^n, x_2^n, \ldots, x_{n-1}^n, x_n - 1, x_{n+1}, x_{n+2}, \ldots) \subset k[x_1, x_2, x_3, \ldots][1/x_n].$$

Note that $I_n k[x_1, x_2, x_3, \ldots][1/x_n, x_m] = (1)$ for any $m \neq n$. Hence the quasi-coherent ideals $I_n$ on $D(x_n)$ agree on $D(x_n, x_m)$, namely $I_n|_{D(x_n, x_m)} = O_D(x_n, x_m)$ if $n \neq m$. Hence these ideals glue to a quasi-coherent sheaf of ideals $\mathcal{I} \subset O_U$. Let $Z \subset U$ be the closed subscheme corresponding to $\mathcal{I}$. Thus $Z \to X$ is an immersion.

We claim that we cannot factor $Z \to X$ as $Z \to \overline{Z} \to X$, where $\overline{Z} \to X$ is closed and $Z \to \overline{Z}$ is open. Namely, $\overline{Z}$ would have to be defined by an ideal $I \subset k[x_1, x_2, x_3, \ldots]$ such that $I_n = Ik[x_1, x_2, x_3, \ldots][1/x_n]$. But the only element $f \in k[x_1, x_2, x_3, \ldots]$ which ends up in all $I_n$ is 0! Hence $I$ does not exist.

### 20. Nonexistence of suitable opens

This section complements the results of Properties, Section 27.

Let $k$ be a field and let $A = k[z_1, z_2, z_3, \ldots]/I$ where $I$ is the ideal generated by all pairwise products $z_iz_j$, $i \neq j$, $i, j \in \mathbb{N}$. Set $S = \text{Spec}(A)$. Let $s \in S$ be the closed point corresponding to the maximal ideal $(z_i)$. We claim there is no quasi-compact open $V \subset S \setminus \{s\}$ which is dense in $S \setminus \{s\}$. Note that $S \setminus \{s\} = \bigcup D(z_i)$. Each $D(z_i)$ is open and irreducible with generic point $\eta_i$. We conclude that $\eta_i \in V$
for all \( i \). However, a principal affine open of \( S \setminus \{ s \} \) is of the form \( D(f) \) where \( f \in (z_1, z_2, \ldots) \). Then \( f \in (z_1, \ldots, z_n) \) for some \( n \) and we see that \( D(f) \) contains only finitely many of the points \( \eta_i \). Thus \( V \) cannot be quasi-compact.

Let \( k \) be a field and let \( B = k[x, z_1, z_2, z_3, \ldots]/J \) where \( J \) is the ideal generated by the products \( xz_i, i \in \mathbb{N} \) and by all pairwise products \( z_i z_j, i \neq j, i, j \in \mathbb{N} \).

Set \( T = \text{Spec}(B) \). Consider the principal open \( U = D(x) \). We claim there is no quasi-compact open \( V \subset S \) such that \( V \cap U = \emptyset \) and \( V \cup U \) is dense in \( S \). Let \( t \in T \) be the closed point corresponding to the maximal ideal \( (x, z_i) \). The closure of \( U \) in \( T \) is \( \overline{U} = U \cup \{ t \} \). Hence \( V \subset \bigcup_j D(z_j) \) is a quasi-compact open. By the arguments of the previous paragraph we see that \( V \) cannot be dense in \( \bigcup D(z_j) \).

**Lemma 20.1.** Nonexistence quasi-compact opens of affines:

1. There exist an affine scheme \( S \) and affine open \( U \subset S \) such that there is no quasi-compact open \( V \subset S \) with \( U \cap V = \emptyset \) and \( U \cup V \) dense in \( S \).
2. There exists an affine scheme \( S \) and a closed point \( s \in S \) such that \( S \setminus \{ s \} \) does not contain a quasi-compact dense open.

**Proof.** See discussion above. \( \Box \)

Let \( X \) be the glueing of two copies of the affine scheme \( T \) (see above) along the affine open \( U \). Thus there is a morphism \( \pi : X \to T \) and \( X = U_1 \cup U_2 \) such that \( \pi \) maps \( U_i \) isomorphically to \( T \) and \( U_1 \cap U_2 \) isomorphically to \( U \). Note that \( X \) is quasi-separated (by Schemes, Lemma 21.17) and quasi-compact. We claim there does not exist a separated, dense, quasi-compact open \( W \subset X \). Namely, consider the two closed points \( x_1 \in U_1, x_2 \in U_2 \) mapping to the closed point \( t \in T \) introduced above. Let \( \tilde{\eta} \in U_1 \cap U_2 \) be the generic point mapping to the (unique) generic point \( \eta \) of \( U \). Note that \( \tilde{\eta} \rightsquigarrow x_1 \) and \( \tilde{\eta} \rightsquigarrow x_2 \) lying over the specialization \( \eta \rightsquigarrow s \). Since \( \pi_{|W} : W \to T \) is separated we conclude that we cannot have both \( x_1 \) and \( x_2 \in W \) (by the valuative criterion of separatedness Schemes, Lemma 22.2). Say \( x_1 \notin W \). Then \( W \cap U_1 \) is a quasi-compact (as \( X \) is quasi-separated) dense open of \( U_1 \) which does not contain \( x_1 \). Now observe that there exists an isomorphism \( (T, t) \cong (S, s) \) of schemes (by sending \( x \) to \( z_1 \) and \( z_1 \) to \( z_{i+1} \)). Hence by the first paragraph of this section we arrive at a contradiction.

**Lemma 20.2.** There exists a quasi-compact and quasi-separated scheme \( X \) which does not contain a separated quasi-compact dense open.

**Proof.** See discussion above. \( \Box \)

**21. Nonexistence of quasi-compact dense open subscheme**

Let \( X \) be a quasi-compact and quasi-separated algebraic space over a field \( k \). We know that the schematic locus \( X' \subset X \) is a dense open subspace, see Properties of Spaces, Proposition 11.3. In fact, this result holds when \( X \) is reasonable, see Decent Spaces, Proposition 9.1. A natural question is whether one can find a quasi-compact dense open subscheme of \( X \). It turns out this is not possible in general.

Assume the characteristic of \( k \) is not 2. Let \( B = k[x, z_1, z_2, z_3, \ldots]/J \) where \( J \) is the ideal generated by the products \( xz_i, i \in \mathbb{N} \) and by all pairwise products \( z_i z_j, i \neq j, i, j \in \mathbb{N} \). Set \( U = \text{Spec}(B) \). Denote \( 0 \in U \) the closed point all of whose coordinates are zero. Set \( j : R = \Delta \prod \Gamma \to U \times_k U \)
where $\Delta$ is the image of the diagonal morphism of $U$ over $k$ and
\[
\Gamma = \{(x, 0, 0, 0, \ldots), (-x, 0, 0, 0, \ldots) \mid x \in \mathbb{A}^1_k, x \neq 0\}.
\]
It is clear that $s, t : R \to U$ are étale, and hence $j$ is an étale equivalence relation. The quotient $X = U/R$ is an algebraic space (Spaces, Theorem 10.5). Note that $j$ is not an immersion because $(0, 0) \in \Delta$ is in the closure of $\Gamma$. Hence $X$ is not a scheme. On the other hand, $X$ is quasi-separated as $R$ is quasi-compact. Denote $0_X$ the image of the point $0 \in U$. We claim that $X \setminus \{0_X\}$ is a scheme, namely
\[
X \setminus \{0_X\} = \text{Spec} \left( k[x^2, x^{-2}] \right) \coprod \text{Spec} \left( k[z_1, z_2, z_3, \ldots] / (z_1 z_2) \right) \setminus \{0\}
\]
(details omitted). On the other hand, we have seen in Section 20 that the scheme on the right hand side does not contain a quasi-compact dense open.

**Lemma 21.1.** There exists a quasi-compact and quasi-separated algebraic space which does not contain a quasi-compact dense open subscheme.

**Proof.** See discussion above. \(\square\)

Using the construction of Spaces, Example 14.2 in the same manner as we used the construction of Spaces, Example 14.1 above, one obtains an example of a quasi-compact, quasi-separated, and locally separated algebraic space which does not contain a quasi-compact dense open subscheme.

### 22. Affines over algebraic spaces

Suppose that $f : Y \to X$ is a morphism of schemes with $f$ locally of finite type and $Y$ affine. Then there exists an immersion $Y \to \mathbb{A}_X^n$ of $Y$ into affine $n$-space over $X$. See the slightly more general Morphisms, Lemma 40.2.

Now suppose that $f : Y \to X$ is a morphism of algebraic spaces with $f$ locally of finite type and $Y$ an affine scheme. Then it is not true in general that we can find an immersion of $Y$ into affine $n$-space over $X$.

A first (nasty) counter example is $Y = \text{Spec}(k)$ and $X = [\mathbb{A}^1_k / \mathbb{Z}]$ where $k$ is a field of characteristic zero and $\mathbb{Z}$ acts on $\mathbb{A}^1_k$ by translation $(n, t) \mapsto t + n$. Namely, for any morphism $Y \to \mathbb{A}_X^n$ over $X$ we can pullback to the covering $\mathbb{A}^1_k$ of $X$ and we get an infinite disjoint union of $\mathbb{A}^1_k$'s mapping into $\mathbb{A}^{n+1}_k$ which is not an immersion.

A second counter example is $Y = \mathbb{A}^1_k \to X = \mathbb{A}^1_k / R$ with $R = \{(t, t)\} \coprod \{(t, -t), t \neq 0\}$. Namely, in this case the morphism $Y \to \mathbb{A}^n_X$ would be given by some regular functions $f_1, \ldots, f_n$ on $Y$ and hence the fibre product of $Y$ with the covering $\mathbb{A}^{n+1}_k \to \mathbb{A}^n_X$ would be the scheme
\[
\{(f_1(t), \ldots, f_n(t), t)\} \coprod \{(f_1(t), \ldots, f_n(t), -t), t \neq 0\}
\]
with obvious morphism to $\mathbb{A}^{n+1}_k$ which is not an immersion. Note that this gives a counter example with $X$ quasi-separated.

**Lemma 22.1.** There exists a finite type morphism of algebraic spaces $Y \to X$ with $Y$ affine and $X$ quasi-separated, such that there does not exist an immersion $Y \to \mathbb{A}^n_X$ over $X$.

**Proof.** See discussion above. \(\square\)
23. Pushforward of quasi-coherent modules

In Schemes, Lemma 24.1 we proved that \( f^* \) transforms quasi-coherent modules into quasi-coherent modules when \( f \) is quasi-compact and quasi-separated. Here are some examples to show that these conditions are both necessary.

Suppose that \( Y = \text{Spec}(A) \) is an affine scheme and that \( X = \coprod_{n \in \mathbb{N}} Y \). We claim that \( f^* \mathcal{O}_X \) is not quasi-coherent where \( f : X \to Y \) is the obvious morphism. Namely, for \( a \in A \) we have

\[
f^* \mathcal{O}_X(D(a)) = \prod_{n \in \mathbb{N}} A_a
\]

Hence, in order for \( f^* \mathcal{O}_X \) to be quasi-coherent we would need

\[
\prod_{n \in \mathbb{N}} A_a = \left( \prod_{n \in \mathbb{N}} A \right)_{a}
\]

for all \( a \in A \). This isn’t true in general, for example if \( A = \mathbb{Z} \) and \( a = 2 \), then \((1, 1/2, 1/4, 1/8, ...)\) is an element of the left hand side which is not in the right hand side. Note that \( f \) is a non-quasi-compact separated morphism.

Let \( k \) be a field. Set

\[
A = k[t, z, x_1, x_2, x_3, ...]/(tx_1 z, t^2 z x_2^2, t^3 z x_3^2, ...)
\]

Let \( Y = \text{Spec}(A) \). Let \( V \subset Y \) be the open subscheme \( V = D(x_1) \cup D(x_2) \cup ... \).

Let \( X \) be two copies of \( Y \) glued along \( V \). Let \( f : X \to Y \) be the obvious morphism. Then we have an exact sequence

\[
0 \to f_* \mathcal{O}_X \to \mathcal{O}_Y \oplus \mathcal{O}_Y \xrightarrow{(1,-1)} j_* \mathcal{O}_V
\]

where \( j : V \to Y \) is the inclusion morphism. Since

\[
A \to \prod A_{x_n}
\]

is injective (details omitted) we see that \( \Gamma(Y, f_* \mathcal{O}_X) = A \). On the other hand, the kernel of the map

\[
A_t \to \prod A_{tx_n}
\]

is nonzero because it contains the element \( z \). Hence \( \Gamma(D(t), f_* \mathcal{O}_X) \) is strictly bigger than \( A_t \) because it contains \((z,0)\). Thus we see that \( f_* \mathcal{O}_X \) is not quasi-coherent. Note that \( f \) is quasi-compact but non-quasi-separated.

**Lemma 23.1.** Schemes, Lemma 24.1 is sharp in the sense that one can neither drop the assumption of quasi-compactness nor the assumption of quasi-separatedness.

**Proof.** See discussion above. \( \square \)

24. A nonfinite module with finite free rank 1 stalks

Let \( R = \mathbb{Q}[x] \). Set \( M = \sum_{n \in \mathbb{N}} \frac{1}{n!} R \) as a submodule of the fraction field of \( R \). Then \( M \) is not finitely generated, but for every prime \( p \) of \( R \) we have \( M_p \cong R_p \) as an \( R_p \)-module.
25. A finite flat module which is not projective

This is a copy of Algebra, Remark 76.3. It is not true that a finite \( R \)-module which is \( R \)-flat is automatically projective. A counter example is where \( R = C^\infty(\mathbb{R}) \) is the ring of infinitely differentiable functions on \( \mathbb{R} \), and \( M = R_m = R/I \) where \( m = \{ f \in R \mid f(0) = 0 \} \) and \( I = \{ f \in R \mid \exists \epsilon, \epsilon > 0 : f(x) = 0 \ \forall x, |x| < \epsilon \} \).

The morphism \( \text{Spec}(R/I) \to \text{Spec}(R) \) is also an example of a flat closed immersion which is not open.

**Lemma 25.1. Strange flat modules.**

1. There exists a ring \( R \) and a finite flat \( R \)-module \( M \) which is not projective.
2. There exists a closed immersion which is flat but not open.

**Proof.** See discussion above. □

26. A projective module which is not locally free

We give two examples. One where the rank is between 0 and 1 and one where the rank is \( \aleph_0 \).

**Lemma 26.1.** Let \( R \) be a ring. Let \( I \subset R \) be an ideal generated by a countable collection of idempotents. Then \( I \) is projective as an \( R \)-module.

**Proof.** Say \( I = (e_1, e_2, e_3, \ldots) \) with \( e_n \) an idempotent of \( R \). After inductively replacing \( e_{n+1} \) by \( e_n + (1 - e_n)e_{n+1} \) we may assume that \( (e_1) \subset (e_2) \subset (e_3) \subset \ldots \) and hence \( I = \bigcup_{n \geq 1} (e_n) = \text{colim}_n e_n R \). In this case

\[
\text{Hom}_R(I, M) = \text{Hom}_R(\text{colim}_n e_n R, M) = \lim_n \text{Hom}_R(e_n R, M) = \lim_n e_n M
\]

Note that the transition maps \( e_{n+1} M \to e_n M \) are given by multiplication by \( e_n \) are surjective. Hence by Algebra, Lemma 84.4 the functor \( \text{Hom}_R(I, M) \) is exact, i.e., \( I \) is a projective \( R \)-module. □

**Lemma 26.2.** Let \( R \) be a ring. Let \( n \geq 1 \). Let \( M \) be an \( R \)-module generated by \( < n \) elements. Then any \( R \)-module map \( f : R^\oplus n \to M \) has a nonzero kernel.

**Proof.** Choose a surjection \( R^\oplus n^{-1} \to M \). We may lift the map \( f \) to a map \( f' : R^\oplus n \to R^\oplus n^{-1} \). It suffices to prove \( f' \) has a nonzero kernel. The map \( f' : R^\oplus n \to R^\oplus n^{-1} \) is given by a matrix \( A = (a_{ij}) \). If one of the \( a_{ij} \) is not nilpotent, say \( a = a_{ij} \) is not, then we can replace \( A \) by the localization \( A_n \) and we may assume \( a_{ij} \) is a unit. Since if we find a nonzero kernel after localization then there was a nonzero kernel to start with as localization is exact, see Algebra, Proposition 9.12.

In this case we can do a base change on both \( R^\oplus n \) and \( R^\oplus n^{-1} \) and reduce to the case where

\[
A = \begin{pmatrix}
1 & 0 & 0 & \ldots \\
0 & a_{22} & a_{23} & \ldots \\
0 & a_{32} & \ldots & \ldots \\
\ldots & \ldots & \ldots & \ldots
\end{pmatrix}
\]

Hence in this case we win by induction on \( n \). If not then each \( a_{ij} \) is nilpotent. Set \( I = (a_{ij}) \subset R \). Note that \( I^{m+1} = 0 \) for some \( m \geq 0 \). Let \( m \) be the largest integer such that \( I^m \neq 0 \). Then we see that \( (I^m)^{\oplus n} \) is contained in the kernel of the map and we win. □
Suppose that \( P \subset Q \) is an inclusion of \( R \)-modules with \( Q \) a finite \( R \)-module and \( P \) locally free, see Algebra, Definition 76.1. Suppose that \( Q \) can be generated by \( N \) elements as an \( R \)-module. Then it follows from Lemma 26.2 that \( P \) is finite locally free (with the free parts having rank at most \( N \)). And in this case \( P \) is a finite \( R \)-module, see Algebra, Lemma 76.2.

Combining this with the above we see that a non-finitely-generated ideal which is generated by a countable collection of idempotents is projective but not locally free. An explicit example is \( R = \prod_{n \in \mathbb{N}} \mathbb{F}_2 \) and \( I \) the ideal generated by the idempotents
\[
e_n = (1, 1, \ldots, 1, 0, \ldots)
\]
where the sequence of 1’s has length \( n \).

**Lemma 26.3.** There exists a ring \( R \) and an ideal \( I \) such that \( I \) is projective as an \( R \)-module but not locally free as an \( R \)-module.

**Proof.** See above. \( \square \)

**Lemma 26.4.** Let \( K \) be a field. Let \( C_i, i = 1, \ldots, n \) be smooth, projective, geometrically irreducible curves over \( K \). Let \( P_i \in C_i(K) \) be a rational point and let \( Q_i \in C_i \) be a point such that \([\kappa(Q_i) : K] = 2\). Then \([P_1 \times \ldots \times P_n] \) is nonzero in \( A_0(U_1 \times_K \ldots \times_K U_n) \) where \( U_i = C_i \setminus \{Q_i\} \).

**Proof.** There is a degree map \( \text{deg} : A_0(C_1 \times_K \ldots \times_K C_n) \to \mathbb{Z} \) because each \( Q_i \) has degree 2 over \( K \) we see that any zero cycle supported on the “boundary”
\[
C_1 \times_K \ldots \times_K C_n \setminus U_1 \times_K \ldots \times_K U_n
\]
has degree divisible by 2. \( \square \)

We can construct another example of a projective but not locally free module using the lemma above as follows. Let \( C_n, n = 1, 2, 3, \ldots \) be smooth, projective, geometrically irreducible curves over \( Q \) each with a pair of points \( P_n, Q_n \in C_n \) such that \( \kappa(P_n) = Q \) and \( \kappa(Q_n) \) is a quadratic extension of \( Q \). Set \( U_n = C_n \setminus \{Q_n\} \); this is an affine curve. Let \( \mathcal{L}_n \) be the inverse of the ideal sheaf of \( P_n \) on \( U_n \). Note that \( c_1(\mathcal{L}_n) = [P_n] \) in the group of zero cycles \( A_0(U_n) \). Set \( A_n = \Gamma(U_n, \mathcal{O}_{U_n}) \). Let \( L_n = \Gamma(U_n, \mathcal{L}_n) \) which is a locally free module of rank 1 over \( A_n \). Set
\[
B_n = A_1 \otimes_Q A_2 \otimes_Q \ldots \otimes_Q A_n
\]
so that \( \text{Spec}(B_n) = U_1 \times \ldots \times U_n \) all products over \( \text{Spec}(Q) \). For \( i \leq n \) we set
\[
L_{n,i} = A_1 \otimes_Q \ldots \otimes_Q M_i \otimes_Q \ldots \otimes_Q A_n
\]
which is a locally free \( B_n \)-module of rank 1. Note that this is also the global sections of \( \text{pr}_i^* \mathcal{L}_n \). Set
\[
B_\infty = \text{colim}_n B_n \quad \text{and} \quad L_{\infty,i} = \text{colim}_n L_{n,i}
\]
Finally, set
\[
M = \bigoplus_{i \geq 1} L_{\infty,i}.
\]
This is a direct sum of finite locally free modules, hence projective. We claim that \( M \) is not locally free. Namely, suppose that \( f \in B_\infty \) is a nonzero function such that \( M_f \) is free over \( (B_\infty)_f \). Let \( e_1, e_2, \ldots \) be a basis. Choose \( n \geq 1 \) such that \( f \in B_n \). Choose \( m \geq n + 1 \) such that \( e_1, \ldots, e_{n+1} \) are in
\[
\bigoplus_{1 \leq i \leq m} L_{m,i}.
\]
Because the elements $e_1, \ldots, e_{n+1}$ are part of a basis after a faithfully flat base change we conclude that the Chern classes

$$c_i(pr_1^* L_1 \oplus \cdots \oplus pr_m^* L_m), \quad i = m, m - 1, \ldots, m - n$$

are zero in the Chow group of $D(f) \subset U_1 \times \cdots \times U_m$.

Since $f$ is the pullback of a function on $U_1 \times \cdots \times U_n$ this implies in particular that

$$c_{m-n}(\mathcal{O}_W \oplus pr_1^* L_{n+1} \oplus \cdots \oplus pr_{m-n}^* L_m) = 0.$$ 

on the variety $W = (C_{n+1} \times \cdots \times C_m)_{K}$ over the field $K = \mathbb{Q}(C_{1} \times \cdots \times C_n)$. In other words the cycle $[(P_{n+1} \times \cdots \times P_m)_{K}]$ is zero in the Chow group of zero cycles on $W$. This contradicts Lemma 26.4 above because the points $Q_i$, $n+1 \leq i \leq m$ induce corresponding points $Q'_i$ on $(C_n)_{K}$ and as $K/\mathbb{Q}$ is geometrically irreducible we have $[\kappa(Q'_i) : K] = 2$.

**Lemma 26.5.** There exists a countable ring $R$ and a projective module $M$ which is a direct sum of countably many locally free rank 1 modules such that $M$ is not locally free.

**Proof.** See above. \hfill \square

### 27. Zero dimensional local ring with nonzero flat ideal

In [Laz07] and [Laz09] there is an example of a zero dimensional local ring with a nonzero flat ideal. Here is the construction. Let $k$ be a field. Let $X_i, Y_i, i \geq 1$ be variables. Take $R = k[X_i, Y_i]/(X_i - Y_iX_{i+1}, Y_i^2)$. Denote $x_i$, resp. $y_i$ the image of $X_i$, resp. $Y_i$ in this ring. Note that

$$x_i = y_i x_{i+1} = y_i y_{i+1} x_{i+2} = y_i y_{i+1} y_{i+2} x_{i+3} = \ldots$$

in this ring. The ring $R$ has only one prime ideal, namely $\mathfrak{m} = (x_i, y_i)$. We claim that the ideal $I = (x_i)$ is flat as an $R$-module.

Note that the annihilator of $x_i$ in $R$ is the ideal $(x_1, x_2, x_3, \ldots, y_i, y_{i+1}, y_{i+2}, \ldots)$. Consider the $R$-module $M$ generated by elements $e_i$, $i \geq 1$ and relations $e_i = y_i e_{i+1}$. Then $M$ is flat as it is the colimit colim $R$ of copies of $R$ with transition maps

$$R \xrightarrow{y_1} R \xrightarrow{y_2} R \xrightarrow{y_3} \cdots$$

Note that the annihilator of $e_i$ in $M$ is the ideal $(x_1, x_2, x_3, \ldots, y_i, y_{i+1}, y_{i+2}, \ldots)$. Since every element of $M$, resp. $I$ can be written as $f e_i$, resp. $h x_i$ for some $f, h \in R$ we see that the map $M \to I$, $e_i \to x_i$ is an isomorphism and $I$ is flat.

**Lemma 27.1.** There exists a local ring $R$ with a unique prime ideal and a nonzero ideal $I \subset R$ which is a flat $R$-module.

**Proof.** See discussion above. \hfill \square
28. An epimorphism of zero-dimensional rings which is not surjective

In [Laz08] and [Laz09] one can find the following example. Let $k$ be a field. Consider the ring homomorphism

$$k[x_1, x_2, \ldots, z_1, z_2, \ldots]/(x_i^4, z_i^4) \to k[x_1, x_2, \ldots, y_1, y_2, \ldots]/(x_i^4, y_i - x_{i+1}y_{i+1}^2)$$

which maps $x_i$ to $x_i$ and $z_i$ to $x_iy_i$. Note that $y_i^{i+1}$ is zero in the right hand side but that $y_i$ is not zero (details omitted). This map is not surjective: we can think of the above as a map of $\mathbb{Z}$-graded algebras by setting $\text{deg}(x_i) = -1$, $\text{deg}(z_i) = 0$, and $\text{deg}(y_i) = 1$ and then it is clear that $y_1$ is not in the image. Finally, the map is an epimorphism because

$$y_{i-1} \otimes 1 = x_iy_i^2 \otimes 1 = y_i \otimes x_iy_i = x_iy_i \otimes y_i = 1 \otimes x_iy_i^2.$$ 

hence the tensor product of the target over the source is isomorphic to the target.

**Lemma 28.1.** There exists an epimorphism of local rings of dimension 0 which is not a surjection.

**Proof.** See discussion above. \hfill \Box

29. Finite type, not finitely presented, flat at prime

Let $k$ be a field. Consider the local ring $A_0 = k[x, y][x, y]$. Denote $p_{0,n} = (y + x^n + x^{2n+1})$. This is a prime ideal. Set

$$A = A_0[z_1, z_2, \ldots]/(z_nz_n, z_n(y + x^n + x^{2n+1}))$$

Note that $A \to A_0$ is a surjection whose kernel is an ideal of square zero. Hence $A$ is also a local ring and the prime ideals of $A$ are in one-to-one correspondence with the prime ideals of $A_0$. Denote $p_n$ the prime ideal of $A$ corresponding to $p_{0,n}$. Observe that $p_n$ is the annihilator of $z_n$ in $A$. Let

$$C = A[z]/(xz^2 + z + y)[1 + \frac{1}{2xz + 1}]$$

Note that $A \to C$ is an étale ring map, see Algebra, Example [33.8]. Let $q \subseteq C$ be the maximal ideal generated by $x, y, z$ and all $z_n$. As $A \to C$ is flat we see that the annihilator of $z_n$ in $C$ is $p_nC$. We compute

$$C/p_nC = A_0[z]/(xz^2 + z + y + x^n + x^{2n+1})[1/(2xz + 1)]$$

$$= k[x,y][z]/(xz^2 + z - x^n - x^{2n+1})[1/(2xz + 1)]$$

$$= k[x,y][z]/(z - x^n) \times k[x,y]/(xz + x^{n+1} + 1)[1/(2xz + 1)]$$

$$= k[x](x) \times k(x)$$

because $(z - x^n)(xz + x^{n+1} + 1) = xz^2 + z - x^n - x^{2n+1}$. Hence we see that $p_nC = r_n \cap q_n$ with $r_n = p_nC + (z - x^n)C$ and $q_n = p_nC + (xz + x^{n+1} + 1)C$. Since $q_n + r_n = C$ we also get $p_nC = r_nq_n$. It follows that $q_n$ is the annihilator of $z_n = (z - x^n)z_n$. Observe that on the one hand $r_n \subseteq q$, and on the other hand $q_n + q = C$. This follows for example because $q_n$ is a maximal ideal of $C$ distinct from $q$. Similarly we have $q_n + q_m = C$ for $n \neq m$. At this point we let

$$B = \text{Im}(C \to C_q)$$
We observe that the elements $\zeta_n$ map to zero in $B$ as $xz + x^{n+1} + 1$ is not in $q$. Denote $q' \subseteq B$ the image of $q$. By construction $B$ is a finite type $A$-algebra, with $B_{q'} \cong C_\nu$. In particular we see that $B_q$ is flat over $A$.

We claim there does not exist an element $g' \in B$, $g' \notin q'$ such that $B_{g'}$ is of finite presentation over $A$. We sketch a proof of this claim. Choose an element $g \in C$ which maps to $g' \in B$. Consider the map $C_g \to B_{g'}$. By Algebra, Lemma\[8.9.3\] we see that $B_g$ is finitely presented over $A$ if and only if the kernel of $C_g \to B_{g'}$ is finitely generated. But the element $g \in C$ is not contained in $q$, hence maps to a nonzero element of $A_0[z]/(xz^2 + z + y)$. Hence $g$ can only be contained in finitely many of the prime ideals $q_n$, because the primes $(y + x^n + x^{2n+1}, xz + x^{n+1} + 1)$ are an infinite collection of codimension 1 points of the 2-dimensional irreducible Noetherian space $\text{Spec}(k[x,y,z]/(xz^2 + z + y))$. The map

$$\bigoplus_{q \notin q_n} C/q_n \to C_g, \quad (c_n) \mapsto \sum c_n\zeta_n$$

is injective and its image is the kernel of $C_g \to B_{g'}$. We omit the proof of this statement. (Hint: Write $A = A_0 \oplus I$ as an $A_0$-module where $I$ is the kernel of $A \to A_0$. Similarly, write $C = C_0 \oplus IC$. Write $IC = \bigoplus C\zeta_n \cong \bigoplus(C/\nu_n \oplus C/q_n)$ and study the effect of multiplication by $g$ on the summands.) This concludes the sketch of the proof of the claim. This also proves that $B_{g'}$ is not flat over $A$ for any $g'$ as above. Namely, if it were flat, then the annihilator of the image of $\zeta_n$ in $B_{g'}$ would be $p_nB_{g'}$, and would not contain $z - x^n$.

As a consequence we can answer (negatively) a question posed in [GR71, Part I, Remarques (3.4.7) (v)]. Here is a precise statement.

**Lemma 29.1.** There exists a local ring $A$, a finite type ring map $A \to B$ and a prime $q$ lying over $m_A$ such that $B_q$ is flat over $A$, and for any element $g \in B$, $g \notin q$ the ring $B_g$ is neither finitely presented over $A$ nor flat over $A$.

**Proof.** See discussion above. \qed

### 30. Finite type, flat and not of finite presentation

In this section we give some examples of ring maps and morphisms which are of finite type and flat but not of finite presentation.

Let $R$ be a ring which has an ideal $I$ such that $R/I$ is a finite flat module but not projective, see Section 25 for an explicit example. Note that this means that $I$ is not finitely generated, see Algebra, Lemma\[105.5\]. Note that $I = I^2$, see Algebra, Lemma\[105.2\]. The base ring in our examples will be $R$ and correspondingly the base scheme $S = \text{Spec}(R)$.

Consider the ring map $R \to R \oplus R/I\epsilon$ where $\epsilon^2 = 0$ by convention. This is a finite, flat ring map which is not of finite presentation. All the fibre rings are complete intersections and geometrically irreducible.

Let $A = R[x,y]/(xy, ay; a \in I)$. Note that as an $R$-module we have $A = \bigoplus_{\geq 0} R_y \oplus \bigoplus_{j \geq 0} R/Ix^j$. Hence $R \to A$ is a flat finite type ring map which is not of finite presentation. Each fibre ring is isomorphic to either $\kappa(p)[x,y]/(xy)$ or $\kappa(p)[x]$.

We can turn the previous example into a projective morphism by taking $B = R[X_0, X_1, X_2]/(X_1X_2, aX_2; a \in I)$. In this case $X = \text{Proj}(B) \to S$ is a proper flat morphism which is not of finite presentation such that for each $s \in S$ the fibre $X_s$ is
isomorphic either to $\mathbf{P}^1_*$ or to the closed subscheme of $\mathbf{P}^2_*$ defined by the vanishing of $X_1X_2$ (this is a projective nodal curve of arithmetic genus 0).

Let $M = R \oplus R \oplus R/I$. Set $B = \text{Sym}_R(M)$ the symmetric algebra on $M$. Set $X = \text{Proj}(B)$. Then $X \to S$ is a proper flat morphism, not of finite presentation such that for $s \in S$ the geometric fibre is isomorphic to either $\mathbf{P}^1_*$ or $\mathbf{P}^2_*$. In particular these fibres are smooth and geometrically irreducible.

**Lemma 30.1.** There exist examples of

1. a flat finite type ring map with geometrically irreducible complete intersection fibre rings which is not of finite presentation,
2. a flat finite type ring map with geometrically connected, geometrically reduced, dimension 1, complete intersection fibre rings which is not of finite presentation,
3. a proper flat morphism of schemes $X \to S$ each of whose fibres is isomorphic to either $\mathbf{P}^1_*$ or to the vanishing locus of $X_1X_2$ in $\mathbf{P}^2_*$ which is not of finite presentation, and
4. a proper flat morphism of schemes $X \to S$ each of whose fibres is isomorphic to either $\mathbf{P}^1_*$ or $\mathbf{P}^2_*$ which is not of finite presentation.

**Proof.** See discussion above. \qed

### 31. Topology of a finite type ring map

Let $A \to B$ be a local map of local domains. If $A$ is Noetherian, $A \to B$ is essentially of finite type, and $A/m_A \subset B/m_B$ is finite then there exists a prime $q \subset B$, $q \neq m_B$ such that $A \to B/q$ is the localization of a quasi-finite ring map. See More on Morphisms, Lemma \[35.6\]

In this section we give an example that shows this result is false $A$ is no longer Noetherian. Namely, let $k$ be a field and set

$$A = \{a_0 + a_1x + a_2x^2 + \ldots | a_0 \in k, a_i \in k((y)) \text{ for } i \geq 1\}$$

and

$$C = \{a_0 + a_1x + a_2x^2 + \ldots | a_0 \in k[y], a_i \in k((y)) \text{ for } i \geq 1\}.$$  

The inclusion $A \to C$ is of finite type as $C$ is generated by $y$ over $A$. We claim that $A$ is a local ring with maximal ideal $m = \{a_1x + a_2x^2 + \ldots \in A\}$ and no prime ideals besides $(0)$ and $m$. Namely, an element $f = a_0 + a_1x + a_2x^2 + \ldots$ of $A$ is invertible as soon as $a_0 \neq 0$. If $q \subset A$ is a nonzero prime ideal, and $f = a_0x^i + \ldots \in q$, then using properties of power series one sees that for any $g \in k((y))$ the element $g^{i+1}x^{i+1} \in q$, i.e., $gx \in q$. This proves that $q = m$.

As to the spectrum of the ring $C$, arguing in the same way as above we see that any nonzero prime ideal contains the prime $p = \{a_1x + a_2x^2 + \ldots \in C\}$ which lies over $m$. Thus the only prime of $C$ which lies over $(0)$ is $(0)$. Set $m_C = yC + p$ and $B = C_{m_C}$. Then $A \to B$ is the desired example.

**Lemma 31.1.** There exists a local homomorphism $A \to B$ of local domains which is essentially of finite type and such that $A/m_A \to B/m_B$ is finite such that for every prime $q \neq m_B$ of $B$ the ring map $A \to B/q$ is not the localization of a quasi-finite ring map.

**Proof.** See the discussion above. \qed
32. Pure not universally pure

Let $k$ be a field. Let

$$R = k[[x, xy, xy^2, \ldots]] \subset k[[x, y]].$$

In other words, a power series $f \in k[[x, y]]$ is in $R$ if and only if $f(0, y)$ is a constant. In particular $R[1/x] = k[[x, y]][1/x]$ and $R/xR$ is a local ring with a maximal ideal whose square is zero. Denote $R[y] \subset k[[x, y]]$ the set of power series $f \in k[[x, y]]$ such that $f(0, y)$ is a polynomial in $y$. Then $R \to R[y]$ is a finite type but not finitely presented ring map which induces an isomorphism after inverting $x$. Also there is a surjection $R[y]/xR[y] \to k[y]$ whose kernel has square zero. Consider the finitely presented ring map $R \to S = R[t]/(xt - xy)$. Again $R[1/x] \to S[1/x]$ is an isomorphism and in this case $S/xS \cong (R/xR)[t]/(xy)$ maps onto $k[t]$ with nilpotent kernel. There is a surjection $S \to R[y]$, $t \mapsto y$ which induces an isomorphism on inverting $x$ and a surjection with nilpotent kernel modulo $x$. Hence the kernel of $S \to R[y]$ is locally nilpotent. In particular $S \to R[y]$ is a universal homeomorphism.

First we claim that $S$ is an $S$-module which is relatively pure over $R$. Since on inverting $x$ we obtain an isomorphism we only need to check this at the maximal ideal $m \subset R$. Since $R$ is complete with respect to its maximal ideal it is henselian hence we need only check that every prime $p \subset R$, $p \neq m$, the unique prime $q$ of $S$ lying over $p$ satisfies $mS + q \neq S$. Since $p \neq m$ it corresponds to a unique prime ideal of $k[[x, y]][1/x]$. Hence either $p = (0)$ or $p = (f)$ for some irreducible element $f \in k[[x, y]]$ which is not associated to $x$ (here we use that $k[[x, y]]$ is a UFD – insert future reference here). In the first case $q = (0)$ and the result is clear. In the second case we may multiply $f$ by a unit so that $f \in R[y]$ (Weierstrass preparation; details omitted). Then it is easy to see that $R[y]/fR[y] \cong k[[x, y]]/(f)$ hence $f$ defines a prime ideal of $R[y]$ and $mR[y] + fR[y] \neq R[y]$. Since $S \to R[y]$ is a universal homeomorphism we deduce the desired result for $S$ also.

Second we claim that $S$ is not universally relatively pure over $R$. Namely, to see this it suffices to find a valuation ring $\mathcal{O}$ and a local ring map $R \to \mathcal{O}$ such that $\text{Spec}(R[y] \otimes_R \mathcal{O}) \to \text{Spec}(\mathcal{O})$ does not hit the closed point of $\text{Spec}(\mathcal{O})$. Equivalently, we have to find $\varphi : R \to \mathcal{O}$ such that $\varphi(x) \neq 0$ and $v(\varphi(x)) > v(\varphi(xy))$ where $v$ is the valuation of $\mathcal{O}$. (Because this means that the valuation of $y$ is negative.) To do this consider the ring map

$$R \to \{a_0 + a_1x + a_2x^2 + \ldots \mid a_0 \in k[y^{-1}], a_i \in k((y))\}$$

defined in the obvious way. We can find a valuation ring $\mathcal{O}$ dominating the localization of the right hand side at the maximal ideal $(y^{-1}, x)$ and we win.

**Lemma 32.1.** There exists a morphism of affine schemes of finite presentation $X \to S$ and an $\mathcal{O}_X$-module $\mathcal{F}$ of finite presentation such that $\mathcal{F}$ is pure relative to $S$, but not universally pure relative to $S$.

**Proof.** See discussion above. \hfill \square

33. A formally smooth non-flat ring map

Let $k$ be a field. Consider the $k$-algebra $k[Q]$. This is the $k$-algebra with basis $x_\alpha, \alpha \in Q$ and multiplication determined by $x_\alpha x_\beta = x_{\alpha + \beta}$. (In particular $x_0 = 1$.)
Consider the $k$-algebra homomorphism
\[ k[Q] \longrightarrow k, \quad x_{\alpha} \longmapsto 1. \]
It is surjective with kernel $J$ generated by the elements $x_{\alpha} - 1$. Let us compute $J/J^2$. Note that multiplication by $x_{\alpha}$ on $J/J^2$ is the identity map. Denote $z_{\alpha}$ the class of $x_{\alpha} - 1$ modulo $J^2$. These classes generate $J/J^2$. Since
\[
(x_{\alpha} - 1)(x_{\beta} - 1) = x_{\alpha+\beta} - x_{\alpha} - x_{\beta} + 1 = (x_{\alpha+\beta} - 1) - (x_{\alpha} - 1) - (x_{\beta} - 1)
\]
we see that $z_{\alpha+\beta} = z_{\alpha} + z_{\beta}$ in $J/J^2$. A general element of $J/J^2$ is of the form $\sum \lambda_{\alpha} z_{\alpha}$ with $\lambda_{\alpha} \in k$ (only finitely many nonzero). Note that if the characteristic of $k$ is $p > 0$ then
\[
0 = pz_{\alpha} = z_{\alpha} + \ldots + z_{\alpha} = z_{\alpha}
\]
and we see that $J/J^2 = 0$. If the characteristic of $k$ is zero, then
\[
J/J^2 = Q \otimes_k k \cong k
\]
(details omitted) is not zero.

We claim that $k[Q] \longrightarrow k$ is a formally smooth ring map if the characteristic of $k$ is positive. Namely, suppose given a solid commutative diagram
\[
\begin{array}{ccc}
  k & \longrightarrow & A \\
  \downarrow & & \downarrow \\
  k[Q] & \longrightarrow & A'
\end{array}
\]
with $A' \twoheadrightarrow A$ a surjection whose kernel $I$ has square zero. To show that $k[Q] \longrightarrow k$ is formally smooth we have to prove that $\varphi$ factors through $k$. Since $\varphi(x_{\alpha} - 1)$ maps to zero in $A$ we see that $\varphi$ induces a map $\overline{\varphi} : J/J^2 \rightarrow I$ whose vanishing is the obstruction to the desired factorization. Since $J/J^2 = 0$ if the characteristic is $p > 0$ we get the result we want, i.e., $k[Q] \longrightarrow k$ is formally smooth in this case. Finally, this ring map is not flat, for example as the nonzerodivisor $x_2 - 1$ is mapped to zero.

**Lemma 33.1.** There exists a formally smooth ring map which is not flat.

**Proof.** See discussion above. \qed

### 34. A formally étale non-flat ring map

In this section we give a counterexample to the final sentence in [DG67, 0, Example 19.10.3(i)] (this was not one of the items caught in their later errata lists). Consider $A \longrightarrow A/J$ for a local ring $A$ and a nonzero proper ideal $J$ such that $J^2 = J$ (so $J$ isn’t finitely generated); the valuation ring of an algebraically closed non-archimedean field with $J$ its maximal ideal is a source of such $(A, J)$. These non-flat quotient maps are formally étale. Namely, suppose given a commutative diagram
\[
\begin{array}{ccc}
  A/J & \longrightarrow & R/I \\
  \downarrow & & \downarrow \\
  A & \varphi \longrightarrow & R
\end{array}
\]
where \( I \) is an ideal of the ring \( R \) with \( I^2 = 0 \). Then \( A \to R \) factors uniquely through \( A/J \) because
\[
\varphi(J) = \varphi(J^2) \subset (\varphi(J)A)^2 \subset I^2 = 0.
\]
Hence this also provides a counterexample to the formally étale case of the “structure theorem” for locally finite type and formally étale morphisms in [DG67, IV, Theorem 18.4.6(i)] (but not a counterexample to part (ii), which is what people actually use in practice). The error in the proof of the latter is that the very last step of the proof is to invoke the incorrect [DG67, 0, Example 19.3.10(i)], which is how the counterexample just mentioned creeps in.

**Lemma 34.1.** There exist formally étale nonflat ring maps.

**Proof.** See discussion above.

\[ \square \]

35. A formally étale ring map with nontrivial cotangent complex

Let \( k \) be a field. Consider the ring
\[
R = k[\{x_n\}_{n \geq 1}, \{y_n\}_{n \geq 1}]/(x_1y_1, x_n^m - x_n, y_m^m - y_n)
\]
Let \( A \) be the localization at the maximal ideal generated by all \( x_n, y_n \) and denote \( J \subset A \) the maximal ideal. Set \( B = A/J \). By construction \( J^2 = J \) and hence \( A \to B \) is formally étale (see Section 34). We claim that the element \( x_1 \otimes y_1 \) is a nonzero element in the kernel of
\[
J \otimes_A J \longrightarrow J.
\]
Namely, \( (A, J) \) is the colimit of the localizations \( (A_n, J_n) \) of the rings
\[
R_n = k[x_n, y_n]/(x_n^ny_n)
\]
at their corresponding maximal ideals. Then \( x_1 \otimes y_1 \) corresponds to the element \( x_n^n \otimes y_n^n \in J_n \otimes_A J_n \) and is nonzero (by an explicit computation which we omit). Since \( \otimes \) commutes with colimits we conclude. By [Ill72, III Section 3.3] we see that \( J \) is not weakly regular. Hence by [Ill72, III Proposition 3.3.3] we see that the cotangent complex \( L_{B/A} \) is not zero. In fact, we can be more precise. We have \( H_0(L_{B/A}) = \Omega_{B/A} \) and \( H_1(L_{B/A}) = 0 \) because \( J/J^2 = 0 \). But from the five-term exact sequence of Quillen’s fundamental spectral sequence (see Cotangent, Remark 11.5 or [Rei, Corollary 8.2.6]) and the nonvanishing of \( \text{Tor}^2_{A}(B, B) = \ker(J \otimes_A J \to J) \) we conclude that \( H_2(L_{B/A}) \) is nonzero.

**Lemma 35.1.** There exists a formally étale surjective ring map \( A \to B \) with \( L_{B/A} \) not equal to zero.

**Proof.** See discussion above.

\[ \square \]

36. Ideals generated by sets of idempotents and localization

Let \( R \) be a ring. Consider the ring
\[
B(R) = R[x_n; n \in \mathbb{Z}]/(x_n(x_n - 1), x_nx_m; n \neq m)
\]
It is easy to show that every prime \( q \subset B(R) \) is either of the form
\[
q = pB(R) + (x_n; n \in \mathbb{Z})
\]
or of the form
\[
q = pB(R) + (x_n - 1) + (x_m; n \neq m, m \in \mathbb{Z}).
\]
Hence we see that
\[ \text{Spec}(B(R)) = \text{Spec}(R) \amalg \coprod_{n \in \mathbb{Z}} \text{Spec}(R) \]
where the topology is not just the disjoint union topology. It has the following properties: Each of the copies indexed by \( n \in \mathbb{Z} \) is an open subscheme, namely it is the standard open \( D(x_n) \). The “central” copy of \( \text{Spec}(R) \) is in the closure of the union of any infinitely many of the other copies of \( \text{Spec}(R) \). Note that this last copy of \( \text{Spec}(R) \) is cut out by the ideal \((x_n, n \in \mathbb{Z})\) which is generated by the idempotents \( x_n \). Hence we see that if \( \text{Spec}(R) \) is connected, then the decomposition above is exactly the decomposition of \( \text{Spec}(B(R)) \) into connected components.

Next, let \( A = \mathbb{C}[x,y]/((y - x^2 + 1)(y + x^2 - 1)) \). The spectrum of \( A \) consists of two irreducible components \( C_1 = \text{Spec}(A_1) \), \( C_2 = \text{Spec}(A_2) \) with \( A_1 = \mathbb{C}[x,y]/(y - x^2 + 1) \) and \( A_2 = \mathbb{C}[x,y]/(y + x^2 - 1) \). Note that these are parametrized by \((x, y) = (t, t^2 - 1)\) and \((x, y) = (t, -t^2 + 1)\) which meet in \( P = (-1, 0) \) and \( Q = (1, 0) \).

We can make a twisted version of \( A \) by \( B(A) \) where we glue \( B(A_1) \) to \( B(A_2) \) in the following way: Above \( P \) we let \( x_n \in B(A_1) \otimes \kappa(P) \) correspond to \( x_n \in B(A_2) \otimes \kappa(P) \), but above \( Q \) we let \( x_n \in B(A_1) \otimes \kappa(Q) \) correspond to \( x_{n+1} \in B(A_2) \otimes \kappa(Q) \). Let \( B^{\text{twist}}(A) \) denote the resulting \( A \)-algebra. Details omitted. By construction \( B^{\text{twist}}(A) \) is Zariski locally over \( A \) isomorphic to the untwisted version. Namely, this happens over both the principal open \( \text{Spec}(A) \setminus \{ P \} \) and the principal open \( \text{Spec}(A) \setminus \{ Q \} \). However, our choice of gluing produces enough “monodromy” such that \( \text{Spec}(B^{\text{twist}}(A)) \) is connected (details omitted). Finally, there is a central copy of \( \text{Spec}(A) \rightarrow \text{Spec}(B^{\text{twist}}(A)) \) which gives a closed subscheme whose ideal is Zariski locally on \( B^{\text{twist}}(A) \) cut out by ideals generated by idempotents, but not globally (as \( B^{\text{twist}}(A) \) has no nontrivial idempotents).

**Lemma 36.1.** There exists an affine scheme \( X = \text{Spec}(A) \) and a closed subscheme \( T \subset X \) such that \( T \) is Zariski locally on \( X \) cut out by ideals generated by idempotents, but \( T \) is not cut out by an ideal generated by idempotents.

**Proof.** See above. \( \square \)

### 37. A ring map which identifies local rings which is not ind-étale

Note that the ring map \( R \rightarrow B(R) \) constructed in Section 36 is a colimit of finite products of copies of \( R \). Hence \( R \rightarrow B(R) \) is ind-Zariski, see Pro-étale Cohomology, Definition 4.1. Next, consider the ring map \( A \rightarrow B^{\text{twist}}(A) \) constructed in Section 36. Since this ring map is Zariski locally on \( \text{Spec}(A) \) isomorphic to an ind-Zariski ring map \( R \rightarrow B(R) \) we conclude that it identifies local rings (see Pro-étale Cohomology, Lemma 4.6). The discussion in Section 36 shows there is a section \( B^{\text{twist}}(A) \rightarrow A \) whose kernel is not generated by idempotents. Now, if \( A \rightarrow B^{\text{twist}}(A) \) were ind-étale, i.e., \( B^{\text{twist}}(A) = \text{colim} A_i \) with \( A_i \rightarrow A \) étale, then the kernel of \( A_i \rightarrow A \) would be generated by an idempotent (Algebra, Lemmas 139.9 and 139.10). This would contradict the result mentioned above.

**Lemma 37.1.** There is a ring map \( A \rightarrow B \) which identifies local rings but which is not ind-étale. A fortiori it is not ind-Zariski.

**Proof.** See discussion above. \( \square \)
38. Non flasque quasi-coherent sheaf associated to injective module

For more examples of this type see [BG71, Exposé II, Appendix I] where Illusie explains some examples due to Verdier.

Consider the affine scheme $X = \text{Spec}(A)$ where

$$A = k[x, y, z_1, z_2, \ldots]/(x^n z_n)$$

is the ring from Properties, Example 23.2. Set $I = (x) \subset A$. Consider the quasi-compact open $U = D(x)$ of $X$. We have seen in loc. cit. that there is a section $s \in \mathcal{O}_X(U)$ which does not come from an $A$-module map $I^n \to A$ for any $n \geq 0$.

Let $\alpha : A \to J$ be the embedding of $A$ into an injective $A$-module. Let $Q = J/\alpha(A)$ and denote $\beta : J \to Q$ the quotient map. We claim that the map

$$\Gamma(X, \tilde{J}) \to \Gamma(U, \tilde{J})$$

is not surjective. Namely, we claim that $\alpha(s)$ is not in the image. To see this, we argue by contradiction. So assume that $x \in J$ is an element which restricts to $\alpha(s)$ over $U$. Then $\beta(x) \in Q$ is an element which restricts to 0 over $U$. Hence we know that $I^n \beta(x) = 0$ for some $n$, see Properties, Lemma 23.1. This implies that we get a morphism $\varphi : I^n \to A$, $h \mapsto \alpha^{-1}(hx)$. It is easy to see that this morphism $\varphi$ gives rise to the section $s$ via the map of Properties, Lemma 23.1 which is a contradiction.

**Lemma 38.1.** There exists an affine scheme $X = \text{Spec}(A)$ and an injective $A$-module $J$ such that $\tilde{J}$ is not a flasque sheaf on $X$. Even the restriction $\Gamma(X, \tilde{J}) \to \Gamma(U, \tilde{J})$ with $U$ a standard open need not be surjective.

**Proof.** See above. □

39. A non-separated flat group scheme

Every group scheme over a field is separated, see Groupoids, Lemma 7.2. This is not true for group schemes over a base.

Let $k$ be a field. Let $S = \text{Spec}(k[x]) = A^1_k$. Let $G$ be the affine line with 0 doubled (see Schemes, Example 14.3) seen as a scheme over $S$. Thus a fibre of $G \to S$ is either a singleton or a set with two elements (one in $U$ and one in $V$). Thus we can endow these fibres with the structure of a group (by letting the element in $U$ be the zero of the group structure). More precisely, $G$ has two opens $U, V$ which map isomorphically to $S$ such that $U \cap V$ is mapped isomorphically to $S \setminus \{0\}$. Then

$$G \times_S G = U \times_S U \cup V \times_S U \cup U \times_S V \cup V \times_S V$$

where each piece is isomorphic to $S$. Hence we can define a multiplication $m : G \times_S G \to G$ as the unique $S$-morphism which maps the first and the last piece into $U$ and the two middle pieces into $V$. This matches the pointwise description given above. We omit the verification that this defines a group scheme structure.

**Lemma 39.1.** There exists a flat group scheme of finite type over the affine line which is not separated.

**Proof.** See the discussion above. □

**Lemma 39.2.** There exists a flat group scheme of finite type over the infinite dimensional affine space which is not quasi-separated.
**Proof.** The same construction as above can be carried out with the infinite dimensional affine space \( S = \mathbb{A}^\infty_k = \text{Spec} k[x_1, x_2, \ldots] \) as the base and the origin \( 0 \in S \) corresponding to the maximal ideal \( (x_1, x_2, \ldots) \) as the closed point which is doubled in \( G \). The resulting group scheme \( G \to S \) is not quasi-separated as explained in Schemes, Example [21.4]. \( \square \)

40. A non-flat group scheme with flat identity component

Let \( X \to S \) be a monomorphism of schemes. Let \( G = S \amalg X \). Let \( m : G \times_S G \to G \) be the \( S \)-morphism

\[
G \times_S G = X \times_S X \amalg X \amalg X \amalg S \to G = X \amalg S
\]

which maps the summands \( X \times_S X \) and \( S \) into \( S \) and maps the summands \( X \) into \( X \) by the identity morphism. This defines a group law. To see this we have to show that \( m \circ (m \times \text{id}_G) = m \circ (\text{id}_G \times m) \) as maps \( G \times_S G \times_S G \to G \). Decomposing \( G \times_S G \times_S G \) into components as above, we see that we need to verify this for the restriction to each of the 8-pieces. Each piece is isomorphic to either \( S \), \( X \), \( X \times_S X \), or \( X \times_S X \times_S X \). Moreover, both maps map these pieces to \( S \), \( X \), \( S \), \( X \) respectively. Having said this, the fact that \( X \to S \) is a monomorphism implies that \( X \times_S X \cong X \) and \( X \times_S X \times_S X \cong X \) and that there is in each case exactly one \( S \)-morphism \( S \to S \) or \( X \to X \). Thus we see that \( m \circ (m \times \text{id}_G) = m \circ (\text{id}_G \times m) \).

Thus taking \( X \to S \) to be any nonflat monomorphism of schemes (e.g., a closed immersion) we get an example of a group scheme over a base \( S \) whose identity component is \( S \) (hence flat) but which is not flat.

**Lemma 40.1.** There exists a group scheme \( G \) over a base \( S \) whose identity component is flat over \( S \) but which is not flat over \( S \).

**Proof.** See discussion above. \( \square \)

41. A non-separated group algebraic space over a field

Every group scheme over a field is separated, see Groupoids, Lemma [7.2]. This is not true for group algebraic spaces over a field (but see end of this section for positive results).

Let \( k \) be a field of characteristic zero. Consider the algebraic space \( G = \mathbb{A}^1_k / \mathbb{Z} \) from Spaces, Example [14.8]. By construction \( G \) is the fppf sheaf associated to the presheaf

\[
T \mapsto \Gamma(T, \mathcal{O}_T) / \mathbb{Z}
\]

on the category of schemes over \( k \). The obvious addition rule on the presheaf induces an addition \( m : G \times G \to G \) which turns \( G \) into a group algebraic space over \( \text{Spec}(k) \). Note that \( G \) is not separated (and not even quasi-separated or locally separated). On the other hand \( G \to \text{Spec}(k) \) is of finite type!

**Lemma 41.1.** There exists a group algebraic space of finite type over a field which is not separated (and not even quasi-separated or locally separated).

**Proof.** See discussion above. \( \square \)

Positive results: If the group algebraic space \( G \) is either quasi-separated, or locally separated, or more generally a decent algebraic space, then \( G \) is in fact separated, see More on Groupoids in Spaces, Lemma [7.4]. Moreover, a finite type, separated
group algebraic space over a field is in fact a scheme (insert future reference here). The idea of the proof is that the schematic locus is open dense, see Properties of Spaces, Proposition 10.3 or Decent Spaces, Theorem 9.2. By translating this open we see that every point of \( G \) has an open neighbourhood which is a scheme.

42. Specializations between points in fibre étale morphism

If \( f : X \to Y \) is an étale, or more generally a locally quasi-finite morphism of schemes, then there are no specializations between points of fibres, see Morphisms, Lemma 21.8. However, for morphisms of algebraic spaces this doesn’t hold in general.

To give an example, let \( k \) be a field. Set

\[ P = k[u, u^{-1}, y, \{x_n\}_{n \in \mathbb{Z}}]. \]

Consider the action of \( \mathbb{Z} \) on \( P \) by \( k \)-algebra maps generated by the automorphism \( \tau \) given by the rules \( \tau(u) = u, \tau(y) = uy, \) and \( \tau(x_n) = x_{n+1}. \) For \( d \geq 1 \) set \( I_d = ((1 - u^d)y, x_n - x_{n+d}, n \in \mathbb{Z}). \) Then \( V(I_d) \subset \text{Spec}(P) \) is the fix point locus of \( \tau^d. \) Let \( S \subset P \) be the multiplicative subset generated by \( y \) and all \( 1 - u^d, d \in \mathbb{N}. \) Then we see that \( \mathbb{Z} \) acts freely on \( U = \text{Spec}(S^{-1}P). \) Let \( X = U/\mathbb{Z} \) be the quotient algebraic space, see Spaces, Definition 14.4.

Consider the prime ideals \( \mathfrak{p}_n = (x_n, x_{n+1}, \ldots) \subset S^{-1}P. \) Note that \( \tau(\mathfrak{p}_n) = \mathfrak{p}_{n+1}. \) Hence each of these define point \( \xi_n \in U \) whose image in \( X \) is the same point \( x \) of \( X. \) Moreover we have the specializations

\[ \ldots \rightsquigarrow \xi_n \rightsquigarrow \xi_{n-1} \rightsquigarrow \ldots \]

We conclude that \( U \to X \) is an example of the promised type.

**Lemma 42.1.** There exists an étale morphism of algebraic spaces \( f : X \to Y \) and a nontrivial specialization of points \( x \rightsquigarrow x' \) in \( |X| \) with \( f(x) = f(x') \) in \( |Y|. \)

**Proof.** See discussion above. \( \square \)

43. A torsor which is not an fpf torsor

In Groupoids, Remark 9.3 we raise the question whether any \( G \)-torsor is a \( G \)-torsor for the fpf topology. In this section we show that this is not always the case.

Let \( k \) be a field. All schemes and stacks are over \( k \) in what follows. Let \( G \to \text{Spec}(k) \) be the group scheme

\[ G = (\mu_{2,k})^\infty = \mu_{2,k} \times_k \mu_{2,k} \times_k \mu_{2,k} \times_k \ldots = \varinjlim_n (\mu_{2,k})^n \]

where \( \mu_{2,k} \) is the group scheme of second roots of unity over \( \text{Spec}(k), \) see Groupoids, Example 5.2. As an inverse limit of affine schemes we see that \( G \) is an affine group scheme. In fact it is the spectrum of the ring \( k[t_1, t_2, t_3, \ldots]/(t_i^2 - 1). \) The multiplication map \( m : G \times_k G \to G \) is on the algebra level given by \( t_i \mapsto t_i \otimes t_i. \)

We claim that any \( G \)-torsor over \( k \) is of the form

\[ P = \text{Spec}(k[x_1, x_2, x_3, \ldots]/(x_i^2 - a_i)) \]

for certain \( a_i \in k^* \) and with \( G \)-action \( G \times_k P \to P \) given by \( x_i \mapsto t_i \otimes x_i \) on the algebra level. We omit the proof. Actually for the example we only need that \( P \) is a \( G \)-torsor which is clear since over \( k' = k(\sqrt{a_1}, \sqrt{a_2}, \ldots) \) the scheme \( P \) becomes
isomorphic to $G$ in a $G$-equivariant manner. Note that $P$ is trivial if and only if $k' = k$ since if $P$ has a $k$-rational point then all of the $a_i$ are squares.

We claim that $P$ is an fppf torsor if and only if the field extension $k \subset k' = k(\sqrt{a_1}, \sqrt{a_2}, \ldots)$ is finite. If $k'$ is finite over $k$, then $\{\text{Spec}(k') \to \text{Spec}(k)\}$ is an fppf covering which trivializes $P$ and we see that $P$ is indeed an fppf torsor. Conversely, suppose that $P$ is a $G$-torsor for the fppf topology. This means that there exists an fppf covering $\{S_i \to \text{Spec}(k)\}$ such that each $P_{S_i}$ is trivial. Pick an $i$ such that $S_i$ is not empty. Let $s \in S_i$ be a closed point. By Varieties, Lemma 12.1 the field extension $k \subset \kappa(s)$ is finite, and by construction $P_{\kappa(s)}$ has a $\kappa(s)$-rational point. Thus we see that $k \subset k' \subset \kappa(s)$ and $k'$ is finite over $k$.

To get an explicit example take $k = \mathbb{Q}$ and $a_i = i$ for example (or $a_i$ is the $i$th prime if you like).

**Lemma 43.1.** Let $S$ be a scheme. Let $G$ be a group scheme over $S$. The stack $G$-Principal classifying principal homogeneous $G$-spaces (see Examples of Stacks, Subsection 13.5) and the stack $G$-Torsors classifying fppf $G$-torsors (see Examples of Stacks, Subsection 13.8) are not equivalent in general.

**Proof.** The discussion above shows that the functor $G$-Torsors $\to$ $G$-Principal isn’t essentially surjective in general. $\square$

### 44. Stack with quasi-compact flat covering which is not algebraic

In this section we briefly describe an example due to Brian Conrad. You can find the example online at [this location](#). Our example is slightly different.

Let $k$ be an algebraically closed field. All schemes and stacks are over $k$ in what follows. Let $G \to \text{Spec}(k)$ be an affine group scheme. In Examples of Stacks, Proposition 14.3 we have seen that $\mathcal{X} = [\text{Spec}(k)/G]$ is a stack in groupoids over $(\text{Sch}/\text{Spec}(k))_{fppf}$ which can be described as follows. A 1-morphism $T \to \mathcal{X}$ corresponds by definition to an fppf $G_T$-torsor $P$ over $T$. The diagonal 1-morphism

$$\Delta : \mathcal{X} \longrightarrow \mathcal{X} \times_{\text{Spec}(k)} \mathcal{X}.$$  

is representable and affine. The reason for this is that given any pair of $G_T$-torsors $P_1, P_2$ in the fppf topology over a scheme $S/k$ the scheme $\text{Isom}(P_1, P_2)$ is affine over $T$. The trivial $G$-torsor over $\text{Spec}(k)$ defines a 1-morphism

$$f : \text{Spec}(k) \longrightarrow \mathcal{X}.$$  

We claim that this is a surjective 1-morphism. The reason is simply that by definition for any 1-morphism $T \to \mathcal{X}$ there exists a fppf covering $\{T_i \to T\}$ such that $P_{T_i}$ is isomorphic to the trivial $G_{T_i}$-torsor. Hence the compositions $T_i \to T \to \mathcal{X}$ factor through $f$. Thus it is clear that the projection $T \times_{\mathcal{X}} \text{Spec}(k) \to \mathcal{X}$ is surjective (which is how we define the property that $f$ is surjective, see Algebraic Stacks, Definition 10.1). In a similar way you show that $f$ is quasi-compact and flat (details omitted). We also record here the observation that

$$\text{Spec}(k) \times_{\mathcal{X}} \text{Spec}(k) \cong G$$  

as schemes over $k$. 
Suppose there exists a surjective smooth morphism $p : U \to \mathcal{X}$ where $U$ is a scheme. Consider the fibre product

$$
\begin{array}{ccc}
W & \rightarrow & U \\
\downarrow & & \downarrow \\
\text{Spec}(k) & \rightarrow & \mathcal{X}
\end{array}
$$

Then we see that $W$ is a nonempty smooth scheme over $k$ which hence has a $k$-point. This means that we can factor $f$ through $U$. Hence we obtain

$$G \cong \text{Spec}(k) \times_{\mathcal{X}} \text{Spec}(k) \cong (\text{Spec}(k) \times_k \text{Spec}(k)) \times_{(U \times_k U)} (U \times_{\mathcal{X}} U)$$

and since the projections $U \times_{\mathcal{X}} U \rightarrow U$ were assumed smooth we conclude that $U \times_{\mathcal{X}} U \rightarrow U \times_k U$ is locally of finite type, see Morphisms, Lemma 16.8. It follows that in this case $G$ is locally of finite type over $k$. Altogether we have proved the following lemma (which can be significantly generalized).

**Lemma 44.1.** Let $k$ be a field. Let $G$ be an affine group scheme over $k$. If the stack $[\text{Spec}(k)/G]$ has a smooth covering by a scheme, then $G$ is of finite type over $k$.

**Proof.** See discussion above.

To get an explicit example as in the title of this section, take for example $G = (\mu_{2,k})^\infty$ the group scheme of Section 43, which is not locally of finite type over $k$. By the discussion above we see that $\mathcal{X} = [\text{Spec}(k)/G]$ has properties (1) and (2) of Algebraic Stacks, Definition 12.1, but not property (3). Hence $\mathcal{X}$ is not an algebraic stack. On the other hand, there does exists a scheme $U$ an a surjective, flat, quasi-compact morphism $U \to \mathcal{X}$, namely the morphism $f : \text{Spec}(k) \to \mathcal{X}$ we studied above.

45. Limit preserving on objects, not limit preserving

Let $S$ be a nonempty scheme. Let $\mathcal{G}$ be an injective abelian sheaf on $(\text{Sch}/S)_{fppf}$. We obtain a stack in groupoids

$$\mathcal{G}\text{-Torsors} \rightarrow (\text{Sch}/S)_{fppf}$$

over $S$, see Examples of Stacks, Lemma 13.2. This stack is limit preserving on objects over $(\text{Sch}/S)_{fppf}$ (see Criteria for Representability, Section 5) because every $\mathcal{G}$-torsor is trivial. On the other hand, $\mathcal{G}\text{-Torsors}$ is in general not limit preserving (see Artin’s Axioms, Definition 13.1) as $\mathcal{G}$ need not be limit preserving as a sheaf. For example, take any nonzero injective sheaf $\mathcal{I}$ and set $\mathcal{G} = \prod_{n \in \mathbb{Z}} \mathcal{I}$ to get an example.

**Lemma 45.1.** Let $S$ be a nonempty scheme. There exists a stack in groupoids $p : \mathcal{X} \rightarrow (\text{Sch}/S)_{fppf}$ such that $p$ is limit preserving on objects, but $\mathcal{X}$ is not limit preserving.

**Proof.** See discussion above.
46. A non-algebraic classifying stack

Let $S = \text{Spec}(\mathbb{F}_p)$ and let $\mu_p$ denote the group scheme of $p$th roots of unity over $S$. In Groupoids in Spaces, Section 19 we have introduced the quotient stack $[S/\mu_p]$ and in Examples of Stacks, Section 14 we have shown $[S/\mu_p]$ is the classifying stack for fppf $\mu_p$-torsors: Given a scheme $T$ over $S$ the category $\text{Mor}_S(T, [S/\mu_p])$ is canonically equivalent to the category of fppf $\mu_p$-torsors over $T$. Finally, in Criteria for Representability, Theorem 17.2 we have seen that $[S/\mu_p]$ is an algebraic stack.

Now we can ask the question: “How about the category fibred in groupoids $S$ classifying étale $\mu_p$-torsors?” (In other words $S$ is a category over $\text{Sch}/S$ whose fibre category over a scheme $T$ is the category of étale $\mu_p$-torsors over $T$.)

The first objection is that this isn’t a stack for the fppf topology, because descent for objects isn’t going to hold. For example the $\mu_p$-torsor $\text{Spec}(\mathbb{F}_p(t)[x]/(x^p - t))$ over $T = \text{Spec}(\mathbb{F}_p(T))$ is fppf locally trivial, but not étale locally trivial.

A fix for this first problem is to work with the étale topology and in this case descent for objects does work. Indeed it is true that $S$ is a stack in groupoids over $(\text{Sch}/S)_{\text{étale}}$. Moreover, it is also the case that the diagonal $\Delta : S \to S \times S$ is representable (by schemes). This is true because given two $\mu_p$-torsors (whether they be étale locally trivial or not) the sheaf of isomorphisms between them is representable by a scheme.

Thus we can finally ask if there exists a scheme $U$ and a smooth and surjective 1-morphism $U \to S$. We will show in two ways that this is impossible: by a direct argument (which we advise the reader to skip) and by an argument using a general result.

Direct argument (sketch): Note that the 1-morphism $S \to \text{Spec}(\mathbb{F}_p)$ satisfies the infinitesimal lifting criterion for formal smoothness. This is true because given a first order infinitesimal thickening of schemes $T \to T'$ the kernel of $\mu_p(T') \to \mu_p(T)$ is isomorphic to the sections of the ideal sheaf of $T$ in $T'$, and hence $H^1_{\text{étale}}(T', \mu_p) = H^1_{\text{étale}}(T, \mu_p)$. Moreover, $S$ is a limit preserving stack. Hence if $U \to S$ is smooth, then $U \to \text{Spec}(\mathbb{F}_p)$ is limit preserving and satisfies the infinitesimal lifting criterion for formal smoothness. This implies that $U$ is smooth over $\mathbb{F}_p$. In particular $U$ is reduced, hence $H^1_{\text{étale}}(U, \mu_p) = 0$. Thus $U \to S$ factors as $U \to \text{Spec}(\mathbb{F}_p) \to S$ and the first arrow is smooth. By descent of smoothness, we see that $U \to S$ being smooth would imply $\text{Spec}(\mathbb{F}_p) \to S$ is smooth. However, this is not the case as $\text{Spec}(\mathbb{F}_p) \times_S \text{Spec}(\mathbb{F}_p)$ is $\mu_p$ which is not smooth over $\text{Spec}(\mathbb{F}_p)$.

Structural argument: In Criteria for Representability, Section 19 we have seen that we can think of algebraic stacks as those stacks in groupoids for the étale topology with diagonal representable by algebraic spaces having a smooth covering. Hence if a smooth surjective $U \to S$ exists then $S$ is an algebraic stack, and in particular satisfies descent in the fppf topology. But we’ve seen above that $S$ does not satisfies descent in the fppf topology.

Loosely speaking the arguments above show that the classifying stack in the étale topology for étale locally trivial torsors for a group scheme $G$ over a base $B$ is algebraic if and only if $G$ is smooth over $B$. One of the advantages of working with the fppf topology is that it suffices to assume that $G \to B$ is flat and locally of finite presentation. In fact the quotient stack (for the fppf topology) $[B/G]$ is
algebraic if and only if $G \to B$ is flat and locally of finite presentation, see Criteria for Representability, Lemma [18.3]

47. Sheaf with quasi-compact flat covering which is not algebraic

Consider the functor $F = \mathbf{(P^1)}^\infty$, i.e., for a scheme $T$ the value $F(T)$ is the set of $f = (f_1, f_2, f_3, \ldots)$ where each $f_i : T \to \mathbf{P}^1$ is a morphism of schemes. Note that $\mathbf{P}^1$ satisfies the sheaf property for fpqc coverings, see Descent, Lemma 9.3. A product of sheaves is a sheaf, so $F$ also satisfies the sheaf property for the fpqc topology. The diagonal of $F$ is representable: if $f : T \to F$ and $g : S \to F$ are morphisms, then $T \times_F S$ is the scheme theoretic intersection of the closed subschemes $T \times_{f_i} \mathbf{P}^1$ over $S$. Consider the group scheme $\text{SL}_2$ which comes with a surjective smooth affine morphism $\text{SL}_2 \to \mathbf{P}^1$. Next, consider $U = (\text{SL}_2)^\infty$ with its canonical (product) morphism $U \to F$. Note that $U$ is an affine scheme. We claim the morphism $U \to F$ is flat, surjective, and universally open. Namely, suppose $f : T \to F$ is a morphism. Then $Z = T \times_F U$ is the infinite fibre product of the schemes $Z_i = T \times_{f_i} \mathbf{P}^1$, $\text{SL}_2$ over $T$. Each of the morphisms $Z_i \to T$ is surjective smooth and affine which implies that

$$Z = Z_1 \times_T Z_2 \times_T Z_3 \times_T \ldots$$

is a scheme flat and affine over $Z$. A simple limit argument shows that $Z \to T$ is open as well.

On the other hand, we claim that $F$ isn’t an algebraic space. Namely, if $F$ where an algebraic space it would be a quasi-compact and separated (by our description of fibre products over $F$) algebraic space. Hence cohomology of quasi-coherent sheaves would vanish above a certain cutoff (see Cohomology of Spaces, Proposition 6.2 and remarks preceding it). But clearly by taking the pullback of $\mathcal{O}(-2, -2, \ldots, -2)$ under the projection

$$(\mathbf{P}^1)^\infty \to (\mathbf{P}^1)^n$$

(which has a section) we can obtain a quasi-coherent sheaf whose cohomology is nonzero in degree $n$. Altogether we obtain an answer to a question asked by Anton Geraschenko on mathoverflow.

**Lemma 47.1.** There exists a functor $F : \text{Sch}^{\text{opp}} \to \text{Sets}$ which satisfies the sheaf condition for the fpqc topology, has representable diagonal $\Delta : F \to F \times F$, and such that there exists a surjective, flat, universally open, quasi-compact morphism $U \to F$ where $U$ is a scheme, but such that $F$ is not an algebraic space.

**Proof.** See discussion above. □

48. Sheaves and specializations

In the following we fix a big étale site $\text{Sch}^{\text{étale}}$, as constructed in Topologies, Definition [4.6]. Moreover, a scheme will be an object of this site. Recall that if $x, x'$ are points of a scheme $X$ we say $x$ is a specialization of $x'$ or we write $x' \Rightarrow x$ if $x \in \{x'\}$. This is true in particular if $x = x'$.

Consider the functor $F : \text{Sch}^{\text{étale}} \to \text{Ab}$ defined by the following rules:

$$F(X) = \prod_{x \in X} \prod_{x' \in X, x' \Rightarrow x, x' \neq x} \mathbb{Z}/2\mathbb{Z}$$
Given a scheme $X$ we denote $|X|$ the underlying set of points. An element $a \in F(X)$ will be viewed as a map of sets $|X| \times |X| \to \mathbb{Z}/2\mathbb{Z}$, $(x,x') \mapsto a(x,x')$ which is zero if $x = x'$ or if $x$ is not a specialization of $x'$. Given a morphism of schemes $f : X \to Y$ we define

$$F(f) : F(Y) \longrightarrow F(X)$$

by the rule that for $b \in F(Y)$ we set

$$F(f)(b)(x,x') = \begin{cases} 0 & \text{if } x \text{ is not a specialization of } x' \\ b(f(x), f(x')) & \text{else.} \end{cases}$$

Note that this really does define an element of $F(X)$. We claim that if $f : X \to Y$ and $g : Y \to Z$ are composable morphisms then $F(f \circ g) = F(g \circ f)$. Namely, let $c \in F(Z)$ and let $x' \rightsquigarrow x$ be a specialization of points in $X$, then

$$F(g \circ f)(x,x') = c(g(f(x))), f(x')) = F(g)(F(f)(c))(x,x')$$

because $f(x') \rightsquigarrow f(x)$. (This also works if $f(x) = f(x')$.)

Let $G$ be the sheafification of $F$ in the étale topology.

I claim that if $X$ is a scheme and $x' \rightsquigarrow x$ is a specialization and $x' \neq x$, then $G(X) \neq 0$. Namely, let $a \in F(X)$ be an element such that when we think of $a$ as a function $|X| \times |X| \to \mathbb{Z}/2\mathbb{Z}$ it is nonzero at $(x,x')$. Let $\{f_i : U_i \to X\}$ be an étale covering of $X$. Then we can pick an $i$ and a point $u_i \in U_i$ with $f_i(u_i) = x$. Since generalizations lift along flat morphisms (see Morphisms, Lemma 26.8) we can find a specialization $u'_i \rightsquigarrow u_i$ with $f_i(u'_i) = x'$. By our construction above we see that $F(f_i)(a) \neq 0$. Hence $a$ determines a nonzero element of $G(X)$.

Note that if $X = \text{Spec}(k)$ where $k$ is a field (or more generally a ring all of whose prime ideals are maximal), then $F(X) = 0$ and for every étale morphism $U \to X$ we have $F(U) = 0$ because there are no specializations between distinct points in fibres of an étale morphism. Hence $G(X) = 0$.

Suppose that $X \subset X'$ is a thickening, see More on Morphisms, Definition 22.1. Then the category of schemes étale over $X'$ is equivalent to the category of schemes étale over $X$ by the base change functor $U' \mapsto U = U' \times_{X'} X$, see Étale Cohomology, Theorem 46.1. Since it is always the case that $F(U) = F(U')$ in this situation we see that also $G(X') = G(X)$.

As a variant we can consider the presheaf $F_n$ which associates to a scheme $X$ the collection of maps $a : |X|^{n+1} \to \mathbb{Z}/2\mathbb{Z}$ where $a(x_0,\ldots,x_n)$ is nonzero only if $x_n \rightsquigarrow \cdots \rightsquigarrow x_0$ is a sequence of specializations and $x_n \neq x_{n-1} \neq \ldots \neq x_0$. Let $G_n$ be the sheaf associated to $F_n$. In exactly the same way as above one shows that $G_n$ is nonzero if $\dim(X) \geq n$ and is zero if $\dim(X) < n$.

**Lemma 48.1.** There exists a sheaf of abelian groups $G$ on $\text{Sch}_{\text{étale}}$ with the following properties

1. $G(X) = 0$ whenever $\dim(X) < n$,
2. $G(X)$ is not zero if $\dim(X) \geq n$, and
3. if $X \subset X'$ is a thickening, then $G(X) = G(X')$.

**Proof.** See the discussion above.

**Remark 48.2.** Here are some remarks:

1. The presheaves $F$ and $F_n$ are separated presheaves.
(2) It turns out that $F$, $F_n$ are not sheaves.
(3) One can show that $G$, $G_n$ is actually a sheaf for the fppf topology.

We will prove these results if we need them.

49. Sheaves and constructible functions

In the following we fix a big étale site $\text{Sch}_{\text{étale}}$ as constructed in Topologies, Definition 4.6. Moreover, a scheme will be an object of this site. In this section we say that a constructible partition of a scheme $X$ is a locally finite disjoint union decomposition $X = \coprod_{i \in I} X_i$ such that each $X_i \subset X$ is a locally constructible subset of $X$. Locally finite means that for any quasi-compact open $U \subset X$ there are only finitely many $i \in I$ such that $X_i \cap U$ is not empty. Note that if $f : X \to Y$ is a morphism of schemes and $Y = \coprod Y_j$ is a constructible partition, then $X = \coprod f^{-1}(Y_j)$ is a constructible partition of $X$. Given a set $S$ and a scheme $X$ a constructible function $f : |X| \to S$ is a map such that $X = \coprod_{s \in S} f^{-1}(s)$ is a constructible partition of $X$. If $G$ is an (abstract group) and $a, b : |X| \to G$ are constructible functions, then $ab : |X| \to G, x \mapsto a(x)b(x)$ is a constructible function too. The reason is that given any two constructible partitions there is a third one refining both.

Let $A$ be any abelian group. For any scheme $X$ we define

$$F(X) = \frac{\{a : |X| \to A \mid a \text{ is a constructible function}\}}{\text{locally constant functions } |X| \to A}$$

We think of an element $a$ of $F(X)$ simply as a function well defined up to adding a locally constant one. Given a morphism of schemes $f : X \to Y$ and an element $b \in F(Y)$, then we define $F(f)(b) = b \circ f$. Thus $F$ is a presheaf on $\text{Sch}_{\text{étale}}$.

Note that if $\{f_i : U_i \to X\}$ is an fppf covering, and $a \in F(X)$ is such that $F(f_i)(a) = 0$ in $F(U_i)$, then $a \circ f_i$ is a locally constant function for each $i$. This means in turn that $a$ is a locally constant function as the morphisms $f_i$ are open. Hence $a = 0$ in $F(X)$. Thus we see that $F$ is a separated presheaf (in the fppf topology hence a fortiori in the étale topology).

Let $G$ be the sheafification of $F$ in the étale topology. Since $F$ is separated, and since $F(X) \neq 0$ for example when $X$ is the spectrum of a discrete valuation ring, we see that $G$ is not zero.

Let $X = \text{Spec}(k)$ where $k$ is a field. Then any étale covering of $X$ can be dominated by a covering $\{\text{Spec}(k') \to \text{Spec}(k)\}$ with $k \subset k'$ a finite separable extension of fields. Since $F(\text{Spec}(k')) = 0$ we see that $G(X) = 0$.

Suppose that $X \subset X'$ is a thickening, see More on Morphisms, Definition 2.1. Then the category of schemes étale over $X'$ is equivalent to the category of schemes étale over $X$ by the base change functor $U' \mapsto U = U' \times_{X'} X$, see Étale Cohomology, Theorem 46.1. Since $F(U) = F(U')$ in this situation we see that also $G(X) = G(X')$.

The sheaf $G$ is limit preserving, see Limits of Spaces, Definition 3.1. Namely, let $R$ be a ring which is written as a directed colimit $R = \text{colim}_i R_i$ of rings. Set $X = \text{Spec}(R)$ and $X_i = \text{Spec}(R_i)$, so that $X = \text{lim}_i X_i$. Then $G(X) = \text{colim}_i G(X_i)$. To prove this one first proves that a constructible partition of $\text{Spec}(R)$ comes from a constructible partitions of some $\text{Spec}(R_i)$. Hence the result for $F$. To get the result
for the sheafification, use that any étale ring map $R \to R'$ comes from an étale ring map $R_i \to R'_i$ for some $i$. Details omitted.

**Lemma 49.1.** There exists a sheaf of abelian groups $G$ on $\text{Sch}_{\text{étale}}$ with the following properties

1. $G(\text{Spec}(k)) = 0$ whenever $k$ is a field,
2. $G$ is limit preserving,
3. if $X \subset X'$ is a thickening, then $G(X) = G(X')$, and
4. $G$ is not zero.

**Proof.** See discussion above. □

50. The lisse-étale site is not functorial

The lisse-étale site $X_{\text{lisse,étale}}$ of $X$ is the category of schemes smooth over $X$ endowed with (usual) étale coverings, see Cohomology of Stacks, Section 11. Let $f : X \to Y$ be a morphism of schemes. There is a functor

$$u : Y_{\text{lisse,étale}} \to X_{\text{lisse,étale}}, \quad V/Y \mapsto V \times_Y X$$

which is continuous. Hence we obtain an adjoint pair of functors

$$u^* : \text{Sh}(X_{\text{lisse,étale}}) \to \text{Sh}(Y_{\text{lisse,étale}}), \quad u_* : \text{Sh}(Y_{\text{lisse,étale}}) \to \text{Sh}(X_{\text{lisse,étale}}),$$

see Sites, Section 14. We claim that, in general, $u$ does not define a morphism of sites, see Sites, Definition 15.1. In other words, we claim that $u_*$ is not left exact in general. Note that representable presheaves are sheaves on lisse-étale sites. Hence, by Sites, Lemma 14.5 we see that $u_* h_V = h_{V \times_Y X}$. Now consider two morphisms

$$\begin{array}{ccc}
V_1 & \xrightarrow{a} & V_2 \\
\searrow & & \searrow \\
& Y & \\
\downarrow & & \downarrow \\
& V_2 & \xrightarrow{b} V_1
\end{array}$$

of schemes $V_1, V_2$ smooth over $Y$. Now if $u_*$ is left exact, then we would have

$$u_* \text{Equalizer}(h_a, h_b : h_{V_1} \to h_{V_2}) = \text{Equalizer}(h_{a \times Y X}, h_{b \times Y X} : h_{V_1 \times_Y X} \to h_{V_2 \times_Y X})$$

We will take the morphisms $a, b : V_1 \to V_2$ such that there exists no morphism from a scheme smooth over $Y$ into $(a = b) \subset V_1$, i.e., such that the left hand side is the empty sheaf, but such that after base change to $X$ the equalizer is nonempty and smooth over $X$. A silly example is to take $X = \text{Spec}(\mathbb{F}_p)$, $Y = \text{Spec}(\mathbb{Z})$ and $V_1 = V_2 = \mathbb{A}^2_\mathbb{Z}$ with morphisms $a(x) = x$ and $b(x) = x + p$. Note that the equalizer of $a$ and $b$ is the fibre of $\mathbb{A}^2_\mathbb{Z}$ over $(p)$.

**Lemma 50.1.** The lisse-étale site is not functorial, even for morphisms of schemes.

**Proof.** See discussion above. □

51. Derived pushforward of quasi-coherent modules

Let $k$ be a field of characteristic $p > 0$. Let $S = \text{Spec}(k[x])$. Let $G = \mathbb{Z}/p\mathbb{Z}$ viewed either as an abstract group or as a constant group scheme over $S$. Consider the algebraic stack $\mathcal{X} = [S/G]$ where $G$ acts trivially on $S$, see Examples of Stacks, Remark 14.4 and Criteria for Representability, Lemma 18.3. Consider the structure morphism

$$f : \mathcal{X} \to S$$
This morphism is quasi-compact and quasi-separated. Hence we get a functor
\[ Rf_{QCoh, *} : D^+_{QCoh}(\mathcal{O}_X) \to D^+_{QCoh}(\mathcal{O}_S), \]
see Derived Categories of Stacks, Proposition 5.1. Let’s compute \( Rf_{QCoh, *}\mathcal{O}_X \).
Since \( D_{QCoh}(\mathcal{O}_S) \) is equivalent to the derived category of \( k[x] \)-modules (see Derived Categories of Schemes, Lemma 3.4), this is equivalent to computing \( R\Gamma(X, \mathcal{O}_X) \). For this we can use the covering \( S \to X \) and the spectral sequence
\[ H^q(S \times_X \ldots \times_X S, O) \Rightarrow H^{p+q}(X, \mathcal{O}_X) \]
see Cohomology of Stacks, Proposition 10.4. Note that
\[ S \times_X \ldots \times_X S = S \times G^p \]
which is affine. Thus the complex
\[ k[x] \to \text{Map}(G, k[x]) \to \text{Map}(G^2, k[x]) \to \ldots \]
computes \( R\Gamma(X, \mathcal{O}_X) \). Here for \( \varphi \in \text{Map}(G^{p-1}, k[x]) \) its differential is the map which sends \((g_1, \ldots, g_p)\) to
\[ \varphi(g_2, \ldots, g_p) + \sum_{i=1}^{p-1} (-1)^i \varphi(g_1, \ldots, g_i + g_{i+1}, \ldots, g_p) + (-1)^p \varphi(g_1, \ldots, g_{p-1}). \]
This is just the complex computing the group cohomology of \( G \) acting trivially on \( k[x] \) (insert future reference here). The cohomology of the cyclic group \( G \) on \( k[x] \) is exactly one copy of \( k[x] \) in each cohomological degree \( \geq 0 \) (insert future reference here). We conclude that
\[ Rf_*\mathcal{O}_X = \bigoplus_{n \geq 0} \mathcal{O}_S[-n] \]
Now, consider the complex
\[ E = \bigoplus_{m \geq 0} \mathcal{O}_X[m] \]
This is an object of \( D_{QCoh}(\mathcal{O}_X) \). We interrupt the discussion for a general result.

**Lemma 51.1.** Let \( X \) be an algebraic stack. Let \( K \) be an object of \( D(\mathcal{O}_X) \) whose cohomology sheaves are locally quasi-coherent (Sheaves on Stacks, Definition 11.4) and satisfy the flat base change property (Cohomology of Stacks, Definition 7.1). Then there exists a distinguished triangle
\[ K \to \prod_{n \geq 0} \tau_{\geq -n} K \to \prod_{n \geq 0} \tau_{\geq -n} K \to K[1] \]
in \( D(\mathcal{O}_X) \). In other words, \( K \) is the derived limit of its canonical truncations.

**Proof.** Recall that we work on the “big fppf site” \( X_{fppf} \) of \( X \) (by our conventions for sheaves of \( \mathcal{O}_X \)-modules in the chapters Sheaves on Stacks and Cohomology on Stacks). Let \( \mathcal{B} \) be the set of objects \( x \) of \( X_{fppf} \) which lie over an affine scheme \( U \). Combining Sheaves on Stacks, Lemmas \( 22.2 \) \( 15.1 \) Descent, Lemma \( 8.4 \) and Cohomology of Schemes, Lemma \( 2.2 \) we see that \( H^p(x, \mathcal{F}) = 0 \) if \( \mathcal{F} \) is locally quasi-coherent and \( x \in \mathcal{B} \). Now the claim follows from Cohomology on Sites, Lemma \( 22.3 \). \( \square \)

**Lemma 51.2.** Let \( X \) be an algebraic stack. If \( \mathcal{F}_n \) is a collection of locally quasi-coherent sheaves with the flat base change property on \( X \), then \( \oplus_n \mathcal{F}_n[n] \to \prod_n \mathcal{F}_n[n] \) is an isomorphism in \( D(\mathcal{O}_X) \).
**Proof.** This is true because by Lemma 51.1 we see that the direct sum is isomorphic to the product.

We continue our discussion. Since a quasi-coherent module is locally quasi-coherent and satisfies the flat base change property (Sheaves on Stacks, Lemma 11.5) we get

\[ E = \prod_{m \geq 0} \mathcal{O}_X[m] \]

Since cohomology commutes with limits we see that

\[ Rf_* E = \prod_{m \geq 0} \left( \bigoplus_{n \geq 0} \mathcal{O}_S[m - n] \right) \]

Note that this complex is not an object of \( D_{QCoh}(\mathcal{O}_S) \) because the cohomology sheaf in degree 0 is an infinite product of copies of \( \mathcal{O}_S \) which is not even a locally quasi-coherent \( \mathcal{O}_S \)-module.

**Lemma 51.3.** A quasi-compact and quasi-separated morphism \( f : \mathcal{X} \to \mathcal{Y} \) of algebraic stacks need not induce a functor \( Rf_* : D_{QCoh}(\mathcal{O}_X) \to D_{QCoh}(\mathcal{O}_Y) \).

**Proof.** See discussion above.

52. A big abelian category

The purpose of this section is to give an example of a “big” abelian category \( A \) and objects \( M, N \) such that the collection of isomorphism classes of extensions \( \text{Ext}_A(M, N) \) is not a set. The example is due to Freyd, see [Freyd, page 131, Exercise A].

We define \( A \) as follows. An object of \( A \) consists of a triple \((M, \alpha, f)\) where \( M \) is an abelian group and \( \alpha \) is an ordinal and \( f : \alpha \to \text{End}(M) \) is a map. A morphism \((M, \alpha, f) \to (M', \alpha', f')\) is given by a homomorphism of abelian groups \( \varphi : M \to M' \) such that for any ordinal \( \beta \) we have

\[ \varphi \circ f(\beta) = f'(\beta) \circ \varphi \]

Here the rule is that we set \( f(\beta) = 0 \) if \( \beta \) is not in \( \alpha \) and similarly we set \( f'(\beta) \) equal to zero if \( \beta \) is not an element of \( \alpha' \). We omit the verification that the category so defined is abelian.

Consider the object \( Z = (\mathbb{Z}, \emptyset, f) \), i.e., all the operators are zero. The observation is that computed in \( A \) the group \( \text{Ext}_A^1(Z, Z) \) is a proper class and not a set. Namely, for each ordinal \( \alpha \) we can find an extension \((M, \alpha + 1, f)\) of \( Z \) by \( Z \) whose underlying group is \( M = \mathbb{Z} \oplus \mathbb{Z} \) and where the value of \( f \) is always zero except for

\[ f(\alpha) = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \]

This clearly produces a proper class of isomorphism classes of extensions. In particular, the derived category of \( A \) has proper classes for its collections of morphism, see Derived Categories, Lemma 27.6. This means that some care has to be exercised when defining Verdier quotients of triangulated categories.

**Lemma 52.1.** There exists a “big” abelian category \( A \) whose Ext-groups are proper classes.

**Proof.** See discussion above.
53. Weakly associated points and scheme theoretic density

Let $k$ be a field. Let $R = k[z, x_i, y_i]/(z^2, z x_i y_i)$ where $i$ runs over the elements of $\mathbb{N}$. Note that $R = R_0 \oplus M_0$ where $R_0 = k[x_i, y_i]$ is a subring and $M_0$ is an ideal of square zero with $M_0 \cong R_0/(x_i y_i)$ as $R_0$-module. The prime $p = (z, x_i)$ is weakly associated to $R$ as an $R$-module (Algebra, Definition 65.1). Indeed, the element $z$ in $R_p$ is nonzero but annihilated by $p R_p$. On the other hand, consider the open subscheme

$$U = \bigcup D(x_i) \subset \text{Spec}(R) = S$$

We claim that $U \subset S$ is scheme theoretically dense (Morphisms, Definition 7.1). To prove this it suffices to show that $\mathcal{O}_S \to j_* \mathcal{O}_U$ is injective where $j : U \to S$ is the inclusion morphism, see Morphisms, Lemma 7.5. Translated back into algebra, we have to show that for all $g \in R$ the map

$$R_g \longrightarrow \prod R_{x_i,g}$$

is injective. Write $g = g_0 + m_0$ with $g_0 \in R_0$ and $m_0 \in M_0$. Then $R_g = R_{g_0}$ (details omitted). Hence we may assume $g \in R_0$. We may also assume $g$ is not zero. Now $R_g = (R_0)_g \oplus (M_0)_g$. Since $R_0$ is a domain, the map $(R_0)_g \rightarrow \prod (R_0)_{x_i,g}$ is injective. If $g \in (x_i y_i)$ then $(M_0)_g = 0$ and there is nothing to prove. If $g \notin (x_i y_i)$ then, since $(x_i y_i)$ is a radical ideal of $R_0$, we have to show that $M_0 \rightarrow \prod (M_0)_{x_i,g}$ is injective. The kernel of $R_0 \rightarrow M_0 \to (M_0)_{y_n}$ is $(x_i y_i, y_n)$. Since $(x_i y_i, y_n)$ is a radical ideal, if $g \notin (x_i y_i, y_n)$ then the kernel of $R_0 \rightarrow M_0 \to (M_0)_{y_n,g}$ is $(x_i y_i, y_n)$. As $g \notin (x_i y_i, y_n)$ for all $n \gg 0$ we conclude that the kernel is contained in $\bigcap_{n \gg 0} (x_i y_i, y_n) = (x_i y_i)$ as desired.

Second example due to Ofer Gabber. Let $k$ be a field and let $R$, resp. $R'$ be the ring of functions $\mathbb{N} \to k$, resp. the ring of eventually constant functions $\mathbb{N} \to k$. Then $\text{Spec}(R)$, resp. $\text{Spec}(R')$ is the Stone–Čech compactification $\beta \mathbb{N}$, resp. the one point compactification $\mathbb{N}^* = \mathbb{N} \cup \{\infty\}$. All points are weakly associated since all primes are minimal in the rings $R$ and $R'$.

**Lemma 53.1.** There exists a reduced scheme $X$ and a schematically dense open $U \subset X$ such that some weakly associated point $x \in X$ is not in $U$.

**Proof.** In the first example we have $p \notin U$ by construction. In Gabber’s examples the schemes $\text{Spec}(R)$ or $\text{Spec}(R')$ are reduced. \qed

54. Example of non-additivity of traces

Let $k$ be a field and let $R = k[\epsilon]$ be the ring of dual numbers over $k$. In other words, $R = k[x]/(x^2)$ and $\epsilon$ is the congruence class of $x$ in $R$. Consider the short exact sequence of complexes

\[
\begin{array}{cccccc}
0 & \longrightarrow & R & \longrightarrow & R & \\
& \begin{array}{c} \ \downarrow \ \end{array} & \begin{array}{c} \ \downarrow \end{array} & & \begin{array}{c} \ \downarrow \ \end{array} & \\
& & & & & \\
& & & & & \\
R & \longrightarrow & R & \longrightarrow & 0
\end{array}
\]

\[\begin{array}{c}
\epsilon
\end{array}\]

\[\begin{array}{c}
1
\end{array}\]

Every element $f \in R$ is of the form $u \epsilon$ where $u$ is a unit and $\epsilon$ is an idempotent. Then Algebra, Lemma 25.5 shows $\text{Spec}(R)$ is Hausdorff. On the other hand, $\mathbb{N}$ with the discrete topology can be viewed as a dense open subset. Given a set map $\mathbb{N} \to X$ to a Hausdorff, quasi-compact topological space $X$, we obtain a ring map $C^0(X; k) \to R$ where $C^0(X; k)$ is the $k$-algebra of locally constant maps $X \to k$. This gives $\text{Spec}(R) \rightarrow \text{Spec}(C^0(X; k)) = X$ proving the universal property.

\[\begin{array}{c}
\text{Here one argues that there is really only one extra maximal ideal in } R'.
\end{array}\]

\[\text{□}\]
Here the columns are the complexes, the first row is placed in degree 0, and the second row in degree 1. Denote the first complex (i.e., the left column) by $A^\bullet$, the second by $B^\bullet$ and the third $C^\bullet$. We claim that the diagram

$\begin{array}{ccc}
A^\bullet & \longrightarrow & B^\bullet \\
1+\epsilon \downarrow & & \downarrow 1 \\
A^\bullet & \longrightarrow & C^\bullet
\end{array}$

commutes in $K(R)$, i.e., is a diagram of complexes commuting up to homotopy. Namely, the square on the right commutes and the one on the left is off by the homotopy $1 : A^1 \to B^0$. On the other hand,

$\text{Tr}_{A^\bullet}(1 + \epsilon) + \text{Tr}_{C^\bullet}(1) \neq \text{Tr}_{B^\bullet}(1)$.

**Lemma 54.1.** There exists a ring $R$, a distinguished triangle $(K, L, M, \alpha, \beta, \gamma)$ in the homotopy category $K(R)$, and an endomorphism $(a, b, c)$ of this distinguished triangle, such that $K, L, M$ are perfect complexes and $\text{Tr}_K(a) + \text{Tr}_M(c) \neq \text{Tr}_L(b)$.

**Proof.** Consider the example above. The map $\gamma : C^\bullet \to A^\bullet[1]$ is given by multiplication by $\epsilon$ in degree 0, see Derived Categories, Definition 10.1. Hence it is also true that

$\begin{array}{ccc}
C^\bullet & \longrightarrow & A^\bullet[1] \\
\downarrow \gamma & & \downarrow \\
C^\bullet & \longrightarrow & A^\bullet[1]
\end{array}$

commutes in $K(R)$ as $\epsilon(1+\epsilon) = \epsilon$. Thus we indeed have a morphism of distinguished triangles. $\square$

55. **Being projective is not local on the base**

In the chapter on descent we have seen that many properties of morphisms are local on the base, even in the fpqc topology. See Descent, Sections [18, 19, and 20] This is not true for projectivity of morphisms.

**Lemma 55.1.** The properties

$\mathcal{P}(f) = \text{"f is projective"}$, and

$\mathcal{P}(f) = \text{"f is quasi-projective"}$

are not Zariski local on the base. A fortiori, they are not fpqc local on the base.

**Proof.** Following Hironaka [Har72, Example B.3.4.1], we define a proper morphism of smooth complex 3-folds $f : V_Y \to Y$ which is Zariski-locally projective, but not projective. Since $f$ is proper and not projective, it is also not quasi-projective.

Let $Y$ be projective 3-space over the complex numbers $\mathbb{C}$. Let $C$ and $D$ be smooth conics in $Y$ such that the closed subscheme $C \cap D$ is reduced and consists of two complex points $P$ and $Q$. (For example, let $C = \{[x, y, z, w] : xy = z^2, w = 0\}$, $D = \{[x, y, z, w] : xy = w^2, z = 0\}$, $P = [1, 0, 0, 0]$, and $Q = [0, 1, 0, 0]$.) On $Y - Q$, first blow up the curve $C$, and then blow up the strict transform of the curve $D$ (Divisors, Definition 21.1). On $Y - P$, first blow up the curve $D$, and then blow up the strict transform of the curve $C$. Over $Y - P - Q$, the two varieties we have constructed are canonically isomorphic, and so we can glue them over $Y - P - Q$. The result is a smooth proper 3-fold $V_Y$ over $\mathbb{C}$. The morphism $f : V_Y \to Y$ is
proper and Zariski-locally projective (since it is a blow-up over \( Y - P \) and over \( Y - Q \)), by Divisors, Lemma \ref{divisors-lem}. We will show that \( V_Y \) is not projective over \( \mathbb{C} \). That will imply that \( f \) is not projective.

To do this, let \( L \) be the inverse image in \( V_Y \) of a complex point of \( C - P - Q \), and \( M \) the inverse image of a complex point of \( D - P - Q \). Then \( L \) and \( M \) are isomorphic to the projective line \( \mathbb{P}^1 \). Next, let \( E \) be the inverse image in \( V_Y \) of \( C \cup D \subset Y \) in \( V_Y \); thus \( E \to C \cup D \) is a proper morphism, with fibers isomorphic to \( \mathbb{P}^1 \) over \( (C \cup D) - \{P, Q\} \). The inverse image of \( P \) in \( E \) is a union of two lines \( L_0 \) and \( M_0 \), and we have rational equivalences of cycles \( L \sim L_0 + M_0 \) and \( M \sim M_0 \) on \( E \) (using that \( C \) and \( D \) are isomorphic to \( \mathbb{P}^1 \)). Note the asymmetry resulting from the order in which we blew up the two curves. Near \( Q \), the opposite happens. So the inverse image of \( Q \) is the union of two lines \( L_0' \) and \( M_0' \), and we have rational equivalences \( L \sim L_0' + M_0' \) and \( M \sim L_0' + M_0' \) on \( E \). Combining these equivalences, we find that \( L_0 + M_0 \sim 0 \) on \( E \) and hence on \( V_Y \). If \( V_Y \) were projective over \( \mathbb{C} \), it would have an ample line bundle \( H \), which would have degree \( > 0 \) on all curves in \( V_Y \). In particular \( H \) would have positive degree on \( L_0 + M_0' \), contradicting that the degree of a line bundle is well-defined on 1-cycles modulo rational equivalence on a proper scheme over a field (Chow Homology, Lemma \ref{chow-homology-lem} and Lemma \ref{chow-homology-lem2}). So \( V_Y \) is not projective over \( \mathbb{C} \).

In different terminology, Hironaka’s 3-fold \( V_Y \) is a small resolution of the blow-up \( Y' \) of \( Y \) along the reduced subscheme \( C \cup D \); here \( Y' \) has two node singularities. If we define \( Z \) by blowing up \( Y \) along \( C \) and then along the strict transform of \( D \), then \( Z \) is a smooth projective 3-fold, and the non-projective 3-fold \( V_Y \) differs from \( Z \) by a “flop” over \( Y - P \).

**56. Descent data for schemes need not be effective, even for a projective morphism**

In the chapter on descent we have seen that descent data for schemes relative to an fpqc morphism are effective for several classes of morphisms. In particular, affine morphisms and more generally quasi-affine morphisms satisfy descent for fpqc coverings (Descent, Lemma \ref{descent-lem}). This is not true for projective morphisms.

**Lemma 56.1.** There is an étale covering \( X \to S \) of schemes and a descent datum \((V/X, \varphi)\) relative to \( X \to S \) such that \( V \to X \) is projective, but the descent datum is not effective in the category of schemes.

**Proof.** We imitate Hironaka’s example of a smooth separated complex algebraic space of dimension 3 which is not a scheme \cite[Example B.3.4.2]{Hartshorne1977}.

Consider the action of the group \( G = \mathbb{Z}/2 = \{1, g\} \) on projective 3-space \( \mathbb{P}^3 \) over the complex numbers by

\[ g[x, y, z, w] = [y, x, w, z]. \]

The action is free outside the two disjoint lines \( L_1 = \{[x, x, z, z]\} \) and \( L_2 = \{[x, -x, z, -z]\} \) in \( \mathbb{P}^3 \). Let \( Y = \mathbb{P}^3 - (L_1 \cup L_2) \). There is a smooth quasi-projective scheme \( S = Y/G \) over \( \mathbb{C} \) such that \( Y \to S \) is a \( G \)-torsor (Groupoids, Definition \ref{groupoids-def}). Explicitly, we can define \( S \) as the image of the open subset \( Y \) in \( \mathbb{P}^3 \) under the
morphism
\[ \mathbb{P}^3 \to \text{Proj } \mathbb{C}[x, y, z, w]^G \]
\[ = \text{Proj } \mathbb{C}[u_0, u_1, v_0, v_1, v_2]/(v_0v_1 - v_2^2), \]
where \( u_0 = x + y, u_1 = z + w, v_0 = (x - y)^2, v_1 = (z - w)^2, \) and \( v_2 = (x - y)(z - w), \) and the ring is graded with \( u_0, u_1 \) in degree 1 and \( v_0, v_1, v_2 \) in degree 2.

Let \( C = \{[x, y, z, w] : xy = z^2, w = 0\} \) and \( D = \{[x, y, z, w] : xy = w^2, z = 0\}. \) These are smooth conic curves in \( \mathbb{P}^3 \), contained in the \( G \)-invariant open subset \( Y \), with \( g(C) = D \). Also, \( C \cap D \) consists of the two points \( P := [1, 0, 0, 0] \) and \( Q := [0, 1, 0, 0] \), and these two points are switched by the action of \( G \).

Let \( V_Y \to Y \) be the scheme which over \( Y - P \) is defined by blowing up \( D \) and then the strict transform of \( C \), and over \( Y - Q \) is defined by blowing up \( C \) and then the strict transform of \( D \). (This is the same construction as in the proof of Lemma \ref{55.1} except that \( Y \) here denotes an open subset of \( \mathbb{P}^3 \) rather than all of \( \mathbb{P}^3 \).

Then the action of \( G \) on \( Y \) lifts to an action of \( G \) on \( V_Y \), which switches the inverse images of \( Y - P \) and \( Y - Q \). This action of \( G \) on \( V_Y \) gives a descent datum \((V_Y/Y, \varphi_Y)\) on \( V_Y \) relative to the \( G \)-torsor \( Y \to S \). The morphism \( V_Y \to Y \) is proper but not projective, as shown in the proof of Lemma \ref{55.1}.

Let \( X \) be the disjoint union of the open subsets \( Y - P \) and \( Y - Q \); then we have surjective etale morphisms \( X \to Y \to S \). Let \( V \) be the pullback of \( V_Y \to Y \) to \( X \); then the morphism \( V_Y \to X \) is projective, since \( V_Y \to Y \) is a blow-up over each of the open subsets \( Y - P \) and \( Y - Q \). Moreover, the descent datum \((V_Y/Y, \varphi_Y)\) pulls back to a descent datum \((V/X, \varphi)\) relative to the etale covering \( X \to S \).

Suppose that this descent datum is effective in the category of schemes. That is, there is a scheme \( U \to S \) which pulls back to the morphism \( V \to X \) together with its descent datum. Then \( U \) would be the quotient of \( V_Y \) by its \( G \)-action.

\[
\begin{array}{ccc}
V_Y & \longrightarrow & V \\
\downarrow & \quad & \downarrow \\
Y & \longrightarrow & X \\
\downarrow & \quad & \downarrow \\
U & \longrightarrow & S
\end{array}
\]

Let \( E \) be the inverse image of \( C \cup D \subset Y \) in \( V_Y \); thus \( E \to C \cup D \) is a proper morphism, with fibers isomorphic to \( \mathbb{P}^1 \) over \((C \cup D) - \{P, Q\}\). The inverse image of \( P \) in \( E \) is a union of two lines \( L_0 \) and \( M_0 \). It follows that the inverse image of \( Q = g(P) \) in \( E \) is the union of two lines \( L'_0 = g(M_0) \) and \( M'_0 = g(L_0) \). As shown in the proof of Lemma \ref{55.1} we have a rational equivalence \( L_0 + M'_0 = L_0 + g(L_0) \sim 0 \) on \( E \).

By descent of closed subschemes, there is a curve \( L_1 \subset U \) (isomorphic to \( \mathbb{P}^1 \)) whose inverse image in \( V_Y \) is \( L_0 \cup g(L_0) \). (Use Descent, Lemma \ref{33.1} noting that a closed immersion is an affine morphism.) Let \( R \) be a complex point of \( L_1 \). Since we assumed that \( U \) is a scheme, we can choose a function \( f \) in the local ring \( O_{U, R} \) that vanishes at \( R \) but not on the whole curve \( L_1 \). Let \( D_{\text{loc}} \) be an irreducible component of the closed subset \( \{f = 0\} \) in \( \text{Spec } O_{U, R} \); then \( D_{\text{loc}} \) has codimension
1. The closure of $D_{loc}$ in $U$ is an irreducible divisor $D_U$ in $U$ which contains the point $R$ but not the whole curve $L_1$. The inverse image of $D_U$ in $V_Y$ is an effective divisor $D$ which intersects $L_0 \cup g(L_0)$ but does not contain either curve $L_0$ or $g(L_0)$.

Since the complex 3-fold $V_Y$ is smooth, $O(D)$ is a line bundle on $V_Y$. We use here that a regular local ring is factorial, or in other words is a UFD, see More on Algebra, Lemma 74.4. The restriction of $O(D)$ to the proper surface $E \subset V_Y$ is a line bundle which has positive degree on the 1-cycle $L_0 + g(L_0)$, by our information on $D$. Since $L_0 + g(L_0) \sim 0$ on $E$, this contradicts that the degree of a line bundle is well-defined on 1-cycles modulo rational equivalence on a proper scheme over a field (Chow Homology, Lemma 20.2 and Lemma 27.2). Therefore the descent datum $(V/X, \varphi)$ is in fact not effective; that is, $U$ does not exist as a scheme. □

In this example, the descent datum is effective in the category of algebraic spaces. More precisely, $U$ exists as a smooth separated algebraic space of dimension 3 over $C$, for example by Algebraic Spaces, Lemma 14.3. Hironaka’s 3-fold $U$ is a small resolution of the blow-up $S'$ of the smooth quasi-projective 3-fold $S$ along the irreducible nodal curve $(C \cup D)/G$; the 3-fold $S'$ has a node singularity. The other small resolution of $S'$ (differing from $U$ by a “flop”) is again an algebraic space which is not a scheme.

57. Derived base change

Let $R \to A$ be a ring map. In More on Algebra, Section 18 we construct a derived base change functor $- \otimes_R A : D(R) \to D(A)$. Next, let $R \to B$ be a second ring map. Picture

$$
\begin{array}{ccc}
B & \longrightarrow & B \otimes_R A \\
\downarrow & & \downarrow \\
R & \longrightarrow & A
\end{array}
$$

Given a $B$-module $M$ the tensor product $M \otimes_R A$ is a $B \otimes_R A$-module. In this section we show there does not exist a “derived base change functor” $D(B) \to D(B \otimes_R A)$.

Let $k$ be a field. Set $R = k[x, y]$. Set $A = R/(xy)$ and $B = R/(x^2)$. The object $B \otimes_R A$ in $D(A)$ is represented by

$$
x^2 : A \longrightarrow A
$$

and we have $H^0(B \otimes_R A) = B \otimes_R A$. We claim that there does not exist an object $E$ of $D(B \otimes_R A)$ mapping to $B \otimes_R A$ in $D(A)$. Namely, for such an $E$ the module $H^0(E)$ would be free, hence $E$ would decompose as $H^0(E)[0] \oplus H^{-1}(E)[1]$. But it is easy to see that $B \otimes_R A$ is not isomorphic to the sum of its cohomology groups in $D(A)$.

**Lemma 57.1.** Let $R \to A$ and $R \to B$ be ring maps. In general there does not exist a functor $T : D(B) \to D(B \otimes_R A)$ of triangulated categories such that a $B$-module $M$ gives an object $T(M)$ of $D(B \otimes_R A)$ which maps to $M \otimes_R A$ under the map $D(B \otimes_R A) \to D(A)$.

**Proof.** See discussion above. □
58. An interesting compact object

Let $R$ be a ring. Let $(A, d)$ be a differential graded $R$-algebra. If $A = R$, then we know that every compact object of $D(A, d) = D(R)$ is represented by a finite complex of finite projective modules. In other words, compact objects are perfect, see More on Algebra, Proposition 60.3. The analogue in the language of differential graded modules would be the question: “Is every compact object of $D(A, d)$ represented by a differential graded $A$-module $P$ which is finite and graded projective?”

For general differential graded algebras, this is not true. Namely, let $k$ be a field of characteristic 2 (so we don’t have to worry about signs). Let $A = k[x, y]/(y^2)$ with

1. $x$ of degree 0
2. $y$ of degree $-1$,
3. $d(x) = 0$, and
4. $d(y) = x^2 + x$.

Then $x : A \to A$ is a projector in $K(A, d)$. Hence we see that

$$A = \text{Ker}(x) \oplus \text{Im}(1 - x)$$

in $K(A, d)$, see Differential Graded Algebra, Lemma 5.4 and Derived Categories, Lemma 4.12. It is clear that $A$ is a compact object of $D(A, d)$ (see Differential Graded Algebra, Lemma 26.2 for a more general statement). Then $\text{Ker}(x)$ is a compact object of $D(A, d)$ as follows from Derived Categories, Lemma 34.2.

Next, suppose that $M$ is a differential graded (right) $A$-module representing $\text{Ker}(x)$ and suppose that $M$ is finite and projective as a graded $A$-module. Because every finite graded projective module over $k[x, y]/(y^2)$ is graded free, we see that $M$ is finite free as a graded $k[x, y]/(y^2)$-module (i.e., when we forget the differential). We set $N = M/M(x^2 + x)$. Consider the exact sequence

$$0 \to M \xrightarrow{x^2 + x} M \to N \to 0$$

Since $x^2 + x$ is of degree 0, in the center of $A$, and $d(x^2 + x) = 0$ we see that this is a short exact sequence of differential graded $A$-modules. Moreover, as $d(y) = x^2 + x$ we see that the differential on $N$ is linear. The maps

$$H^{-1}(N) \to H^0(M) \quad \text{and} \quad H^0(M) \to H^0(N)$$

are isomorphisms as $H^*(M) = H^0(M) = k$ since $M \cong \text{Ker}(x)$ in $D(A, d)$. A computation of the boundary map shows that $H^*(N) = k[x, y]/(x, y^2)$ as a graded module; we omit the details. Since $N$ is a free $k[x, y]/(y^2, x^2 + x)$-module we have a resolution

$$\ldots \to N[2] \xrightarrow{y} N[1] \xrightarrow{x} N \to N/Ny \to 0$$

compatible with differentials. Since $N$ is bounded and since $H^0(N) = k[x, y]/(x, y^2)$ it follows from Homology, Lemma 22.6 that $H^0(N/Ny) = k[x]/(x)$. But as $N/Ny$ is a finite complex of free $k[x]/(x^2 + x) = k \times k$-modules, we see that its cohomology has to have even dimension, a contradiction.

**Lemma 58.1.** There exists a differential graded algebra $(A, d)$ and a compact object $E$ of $D(A, d)$ such that $E$ cannot be represented by a finite and graded projective differential graded $A$-module.

**Proof.** See discussion above.
59. Two differential graded categories

In this section we construct two differential graded categories satisfying axioms (A), (B), and (C) as in Differential Graded Algebra, Situation 20.2 whose objects do not come with a \( \mathbb{Z} \)-grading.

Example I. Let \( X \) be a topological space. Denote \( \mathbb{Z} \) the constant sheaf with value \( \mathbb{Z} \). Let \( A \) be an \( \mathbb{Z} \)-torsor. In this setting we say a sheaf of abelian groups \( \mathcal{F} \) is \( A \)-graded if given a local section \( a \in A(U) \) there is a projector \( p_a : \mathcal{F}|_U \to \mathcal{F}|_U \) such that whenever we have a local isomorphism \( \mathbb{Z}|_U \to A|_U \) then \( \mathcal{F}|_U = \bigoplus_{n \in \mathbb{Z}} p_n(\mathcal{F}) \).

Another way to say this is that locally on \( X \) the abelian sheaf \( \mathcal{F} \) has a \( \mathbb{Z} \)-grading, but on overlaps the different choices of gradings differ by a shift in degree given by the transition functions for the torsor \( A \). We say that a pair \( (\mathcal{F}, d) \) is an \( A \)-graded complex of abelian sheaves, if \( \mathcal{F} \) is an \( A \)-graded abelian sheaf and \( d : \mathcal{F} \to \mathcal{F} \) is a differential, i.e., \( d^2 = 0 \) such that \( p_{a+1} \circ d = d \circ p_a \) for every local section \( a \) of \( A \). In other words, \( d(p_a(\mathcal{F})) \) is contained in \( p_{a+1}(\mathcal{F}) \).

Next, consider the category \( \mathcal{A} \) with

1. objects are \( A \)-graded complexes of abelian sheaves, and
2. for objects \( (\mathcal{F}, d), (\mathcal{G}, d) \) we set

\[
\text{Hom}_{\mathcal{A}}((\mathcal{F}, d), (\mathcal{G}, d)) = \bigoplus \text{Hom}^n(\mathcal{F}, \mathcal{G})
\]

where \( \text{Hom}^n(\mathcal{F}, \mathcal{G}) \) is the group of maps of abelian sheaves \( f \) such that \( f(p_a(\mathcal{F})) \subset p_{a+n}(\mathcal{G}) \) for all local sections \( a \) of \( A \). As differential we take \( d(f) = d \circ f - (-1)^n f \circ d \), see Differential Graded Algebra, Example 19.6.

We omit the verification that this is indeed a differential graded category satisfying (A), (B), and (C). All the properties may be verified locall on \( X \) where one just recovers the differential graded category of complexes of abelian sheaves. Thus we obtain a triangulated category \( K(\mathcal{A}) \).

Twisted derived category of \( X \). Observe that given an object \( (\mathcal{F}, d) \) of \( \mathcal{A} \), there is a well defined \( A \)-graded cohomology sheaf \( H(\mathcal{F}, d) \). Hence it is clear what is meant by a quasi-isomorphism in \( K(\mathcal{A}) \). We can invert quasi-isomorphisms to obtain the derived category \( D(\mathcal{A}) \) of complexes of \( A \)-graded sheaves. If \( A \) is the trivial torsor, then \( D(\mathcal{A}) \) is equal to \( D(X) \), but for nonzero torsors, one obtains a kind of twisted derived category of \( X \).

Example II. Let \( C \) be a smooth curve over a perfect field \( k \) of characteristic 2. Then \( \Omega_{C/k} \) comes endowed with a canonical square root. Namely, we can write \( \Omega_{C/k} = \mathcal{L}^{\otimes 2} \) such that for every local function \( f \) on \( C \) the section \( d(f) \) is equal to \( s^{\otimes 2} \) for some local section \( s \) of \( \mathcal{L} \). The “reason” is that

\[
d(a_0 + a_1 t + \ldots + a_d t^d) = \left( \sum_{i \text{ odd}} a_i^{1/2} t^{(i-1)/2} \right)^2 dt
\]

(insert future reference here). This in particular determines a canonical connection

\[
\nabla_{\text{can}} : \Omega_{C/k} \to \Omega_{C/k} \otimes_{\mathcal{O}_C} \Omega_{C/k}
\]

whose 2-curvature is zero (namely, the unique connection such that the squares have derivative equal to zero). Observe that the category of vector bundles with connections is a tensor category, hence we also obtain canonical connections \( \nabla_{\text{can}} \) on the invertible sheaves \( \Omega_{C/k}^{\otimes n} \) for all \( n \in \mathbb{Z} \).

Let \( \mathcal{A} \) be the category with

(1) objects are pairs \((\mathcal{F}, \nabla)\) consisting of a finite locally free sheaf \(\mathcal{F}\) endowed with a connection

\[
\nabla : \mathcal{F} \to \mathcal{F} \otimes_{\mathcal{O}_C} \Omega_{C/k}
\]

whose 2-curvature is zero, and

(2) morphisms between \((\mathcal{F}, \nabla_{\mathcal{F}})\) and \((\mathcal{G}, \nabla_{\mathcal{G}})\) are given by

\[
\text{Hom}_A((\mathcal{F}, \nabla), (\mathcal{G}, \nabla_{\mathcal{G}})) = \bigoplus \text{Hom}_{\mathcal{O}_C}(\mathcal{F}, \mathcal{G} \otimes_{\mathcal{O}_C} \Omega_{C/k}^{\otimes n})
\]

For an element \(f : \mathcal{F} \to \mathcal{G} \otimes_{\mathcal{O}_C} \Omega_{C/k}^{\otimes n}\) of degree \(n\) we set

\[
d(f) = \nabla_{\mathcal{G} \otimes_{\mathcal{O}_C} \Omega_{C/k}^{\otimes n}} \circ f + f \circ \nabla_{\mathcal{F}}
\]

with suitable identifications.

We omit the verification that this forms a differential graded category with properties (A), (B), (C). Thus we obtain a triangulated homotopy category \(K(A)\).

If \(C = \mathbb{P}^1_k\), then \(K(A)\) is the zero category. However, if \(C\) is a smooth proper curve of genus \(> 1\), then \(K(A)\) is not zero. Namely, suppose that \(\mathcal{N}\) is an invertible sheaf of degree \(0 \leq d < g - 1\) with a nonzero section \(\sigma\). Then set \((\mathcal{F}, \nabla_{\mathcal{F}}) = (\mathcal{O}_C, d)\) and \((\mathcal{G}, \nabla_{\mathcal{G}}) = (\mathcal{N}^{\otimes 2}, \nabla_{\text{can}})\). We see that

\[
\text{Hom}^n_{\mathcal{A}}((\mathcal{F}, \nabla_{\mathcal{F}}), (\mathcal{G}, \nabla_{\mathcal{G}})) = \begin{cases} 
0 & \text{if } n < 0 \\
\Gamma(C, \mathcal{N}^{\otimes 2}) & \text{if } n = 0 \\
\Gamma(C, \mathcal{N}^{\otimes 2} \otimes \Omega_{C/k}^{\otimes n}) & \text{if } n = 1 
\end{cases}
\]

The first 0 because the degree of \(\mathcal{N}^{\otimes 2} \otimes \Omega_{C/k}^{\otimes -1}\) is negative by the condition \(d < g - 1\). Now, the section \(\sigma^{\otimes 2}\) has derivative equal zero, hence the homomorphism group

\[
\text{Hom}_{K(A)}((\mathcal{F}, \nabla_{\mathcal{F}}), (\mathcal{G}, \nabla_{\mathcal{G}}))
\]

is nonzero.

### 60. An example of a non-algebraic Hom-stack

Let \(\mathcal{Y}, \mathcal{Z}\) be algebraic stacks over a scheme \(S\). The Hom-stack \(\text{Mor}_S(\mathcal{Y}, \mathcal{Z})\) is the stack in groupoids over \(S\) whose category of sections over a scheme \(T\) is given by the category

\[
\text{Mor}_T(\mathcal{Y} \times_S T, \mathcal{Z} \times_S T)
\]

whose objects are 1-morphisms and whose morphisms are 2-morphisms. We omit the proof this this is indeed a stack in groupoids over \((\text{Sch}/S)_{fppf}\) (insert future reference here). Of course, in general the Hom-stack will not be algebraic. In this section we give an example where it is not true and where \(\mathcal{Y}\) is representable by a proper flat scheme over \(S\) and \(\mathcal{Z}\) is smooth and proper over \(S\).

Let \(k\) be an algebraically closed field which is not the algebraic closure of a finite field. Let \(S = \text{Spec}(k[[t]])\) and \(S_n = \text{Spec}(k[t]/(t^n)) \subset S\). Let \(f : X \to S\) be a map satisfying the following

1. \(f\) is projective and flat, and its fibres are geometrically connected curves,
2. the fibre \(X_0 = X \times_S S_0\) is a nodal curve with smooth irreducible components whose dual graph has a loop consisting of rational curves,
3. \(X\) is a regular scheme.
To make such a surface $X$ we can take for example
\[ T_0 T_1 T_2 - t (T_3^3 + T_1^3 + T_2^3) = 0 \]
in $\mathbf{P}^2_{k[[t]]}$. Let $A_0$ be a non-zero abelian variety over $k$ for example an elliptic curve. Let $A = A_0 \times_{\text{Spec}(k)} S$ be the constant abelian scheme over $S$ associated to $A_0$. We will show that the stack $X = \text{Mor}_S(X, [S/A])$ is not algebraic.

Recall that $[S/A]$ is on the one hand the quotient stack of $A$ acting trivially on $S$ and on the other hand equal to the stack classifying fppf $A$-torsors, see Examples of Stacks, Proposition 14.3. Observe that $[S/A] = [\text{Spec}(k)/A_0] \times_{\text{Spec}(k)} S$. This allows us to describe the fibre category over a scheme $T$ as follows
\[ X_T = \text{Mor}_S(X, [S/A]) T \]
for any $S$-scheme $T$. In other words, the groupoid $X_T$ is the groupoid of fppf $A_0$-torsors on $X \times_S T$. Before we discuss why $X$ is not an algebraic stack, we need a few lemmas.

**Lemma 60.1.** Let $W$ be a two dimensional regular integral Noetherian scheme with function field $K$. Let $G \to W$ be an abelian scheme. Then the map $H^1_{fppf}(\text{Spec}(K), G) \to H^1_{fppf}(\text{Spec}(K), G)$ is injective.

**Sketch of proof.** Let $P \to W$ be an fppf $G$-torsor which is trivial in the generic point. Then we have a morphism $\text{Spec}(K) \to P$ over $W$ and we can take its scheme theoretic image $Z \subset P$. Since $P \to W$ is proper (as a torsor for a proper group algebraic space over $W$) we see that $Z \to W$ is a proper birational morphism. By Spaces over Fields, Lemma 4.4 the morphism $Z \to W$ is finite away from finitely many closed points of $W$. By (insert future reference on resolving indeterminacies of morphisms by blowing quadratic transformations for surfaces) the irreducible components of the geometric fibres of $Z \to W$ are rational curves. By More on Groupoids in Spaces, Lemma 8.3 there are no nonconstant morphisms from rational curves to group schemes or torsors over such. Hence $Z \to W$ is finite, whence $Z$ is a scheme and $Z \to W$ is an isomorphism by Morphisms, Lemma 48.19. In other words, the torsor $P$ is trivial. \[ \square \]

**Lemma 60.2.** Let $G$ be a smooth commutative group algebraic space over a field $K$. Then $H^1_{fppf}(\text{Spec}(K), G)$ is torsion.

**Proof.** Every $G$-torsor $P$ over $\text{Spec}(K)$ is smooth over $K$ as a form of $G$. Hence $P$ has a point over a finite separable extension $K \subset L$. Say $[L : K] = n$. Let $[n](P)$ denote the $G$-torsor whose class is $n$ times the class of $P$ in $H^1_{fppf}(\text{Spec}(K), G)$. There is a canonical morphism
\[ P \times_{\text{Spec}(K)} \cdots \times_{\text{Spec}(K)} P \to [n](P) \]
of algebraic spaces over $K$. This morphism is symmetric as $G$ is abelian. Hence it factors through the quotient
\[ (P \times_{\text{Spec}(K)} \cdots \times_{\text{Spec}(K)} P)/S_n \]
On the other hand, the morphism $\text{Spec}(L) \to P$ defines a morphism
$$(\text{Spec}(L) \times_{\text{Spec}(K)} \cdots \times_{\text{Spec}(K)} \text{Spec}(L))/S_n \to (P \times_{\text{Spec}(K)} \cdots \times_{\text{Spec}(K)} P)/S_n$$
and the reader can verify that the scheme on the left has a $K$-rational point. Thus we see that $[n](P)$ is the trivial torsor.

To prove $\mathcal{X} = \text{Mor}_S(X, [S/A])$ is not an algebraic stack, by Artin’s Axioms, Lemma 9.4, it is enough to show the following.

**Lemma 60.3.** The canonical map $\mathcal{X}(S) \to \lim \mathcal{X}(S_n)$ is not essentially surjective.

**Sketch of proof.** Unwinding definitions, it is enough to check that $H^1(X, A_0) \to \lim H^1(X_n, A_0)$ is not surjective. As $X$ is regular and projective, by Lemmas 60.2 and 60.1 each $A_0$-torsor over $X$ is torsion. In particular, the group $H^1(X, A_0)$ is torsion. It is thus enough to show: (a) the group $H^1(X_0, A_0)$ is non-torsion, and (b) the maps $H^1(X_{n+1}, A_0) \to H^1(X_n, A_0)$ are surjective for all $n$.

Ad (a). One constructs a nontorsion $A_0$-torsor $P_0$ on the nodal curve $X_0$ by gluing trivial $A_0$-torsors on each component of $X_0$ using non-torsion points on $A_0$ as the isomorphisms over the nodes. More precisely, let $x \in X_0$ be a node which occurs in a loop consisting of rational curves. Let $X'_0 \to X_0$ be the normalization of $X_0$ in $X_0 \setminus \{x\}$. Let $x', x'' \in X'_0$ be the two points mapping to $x_0$. Then we take $A_0 \times_{\text{Spec}(k)} X'_0$ and we identify $A_0 \times x'$ with $A_0 \times \{x''\}$ using translation $A_0 \to A_0$ by a nontorsion point $a_0 \in A_0(k)$ (there is such a nontorsion point as $k$ is algebraically closed and not the algebraic closure of a finite field – this is actually not trivial to prove). One can show that the glueing is an algebraic space (in fact one can show it is a scheme) and that it is an nontorsion $A_0$-torsor over $X_0$. The reason that it is nontorsion is that if $[n](P_0)$ has a section, then that section produces a morphism $s : X'_0 \to A_0$ such that $[n](a_0) = s(x') - s(x'')$ in the group law on $A_0(k)$. However, since the irreducible components of the loop are rational to section $s$ is constant on them (More on Groupoids in Spaces, Lemma 5.3). Hence $s(x') = s(x'')$ and we obtain a contradiction.

Ad (b). Deformation theory shows that the obstruction to deforming an $A_0$-torsor $P_n \to X_n$ to an $A_0$-torsor $P_{n+1} \to X_{n+1}$ lies in $H^2(X_0, \omega)$ for a suitable vector bundle $\omega$ on $X_0$. The latter vanishes as $X_0$ is a curve, proving the claim.

**Proposition 60.4.** The stack $\mathcal{X} = \text{Mor}_S(X, [S/A])$ is not algebraic.

**Proof.** See discussion above.

**Remark 60.5.** Proposition 60.4 contradicts [Aok06a, Theorem 1.1]. The problem is the non-effectivity of formal objects for $\text{Mor}_S(X, [S/A])$. The same problem is mentioned in the Erratum [Aok06a] to [Aok06b]. Unfortunately, the Erratum goes on the assert that $\text{Mor}_S(Y', Z')$ is algebraic if $Z$ is separated, which also contradicts Proposition 60.4 as $[S/A]$ is separated.

61. A counter example to Grothendieck’s existence theorem

Let $k$ be a field and let $A = k[[t]]$. Let $X$ be the glueing of $U = \text{Spec}(A[x])$ and $V = \text{Spec}(A[y])$ by the identification
$$U \setminus \{0_U\} \to V \setminus \{0_V\}.$$
sending \( x \) to \( y \) where \( 0_U \in U \) and \( O_V \in V \) are the points corresponding to the maximal ideals \((x, t)\) and \((y, t)\). Set \( A_n = A/(t^n) \) and set \( X_n = X \times_{\text{Spec}(A)} \text{Spec}(A_n) \). Let \( \mathcal{F}_n \) be the coherent sheaf on \( X_n \) corresponding to the \( A_n[x] \)-module \( A_n[x]/(x) \cong A_n \) and the \( A_n[y] \) module 0 with obvious glueing. Let \( \mathcal{I} \subset \mathcal{O}_X \) be the sheaf of ideals generated by \( t \). Then \( (\mathcal{F}_n) \) is an object of the category \( \text{Coh}_{\text{support proper over } A(X, \mathcal{I})} \) defined in Cohomology of Schemes, Section 21. On the other hand, this object is not in the image of the functor Cohomology of Schemes, Equation 22.6.1. Namely, if it where there would be a finite \( A[x] \)-module \( M \), a finite \( A[y] \)-module \( N \) and an isomorphism \( M[1/t] \cong N[1/t] \) such that \( M/t^n M \cong A_n[x]/(x) \) and \( N/t^n N = 0 \) for all \( n \). It is easy to see that this is impossible.

**Lemma 61.1.** Counter examples to algebraization of coherent sheaves.

1. Grothendieck’s existence theorem as stated in Cohomology of Schemes, Theorem 22.4 is false if we drop the assumption that \( X \to \text{Spec}(A) \) is separated.
2. The stack of coherent sheaves \( \text{Coh}_{X/B} \) of Quot, Theorems 6.5 and 5.12 is in general not algebraic if we drop the assumption that \( X \to S \) is separated.
3. The functor \( \text{Quot}_{\mathcal{F}/X/B} \) of Quot, Proposition 9.3 is not an algebraic space in general if we drop the assumption that \( X \to B \) is separated.

**Proof.** Part (1) we saw above. This shows that \( \text{Coh}_{X/A} \) fails axiom [4] of Artin’s Axioms, Section 12. Hence it cannot be an algebraic stack by Artin’s Axioms, Lemma 9.4. In this way we see that (2) is true. To see (3), note that there are compatible surjections \( \mathcal{O}_{X_n} \to \mathcal{F}_n \) for all \( n \). Thus we see that \( \text{Quot}_{\mathcal{O}/X/X/A} \) fails axiom [4] and we see that (3) is true as before. \( \square \)

### 62. Affine formal algebraic spaces

Let \( K \) be a field and let \( (V_i)_{i \in I} \) be a directed inverse system of nonzero vector spaces over \( K \) with surjective transition maps and with \( \lim V_i = 0 \), see Section 3. Let \( R_i = K \oplus V_i \) as \( K \)-algebra where \( V_i \) is an ideal of square zero. Then \( R_i \) is an inverse system of \( K \)-algebras with surjective transition maps with nilpotent kernels and with \( \lim R_i = K \). The affine formal algebraic space \( X = \text{colim} \text{Spec}(R_i) \) is an example of an affine formal algebraic space which is not McQuillan.

Let \( 0 \to W_i \to V_i \to K \to 0 \) be a system of exact sequences as in Section 3. Let \( A_i = K[V_i]/(ww'; w, w' \in W_i) \). Then there is a compatible system of surjections \( A_i \to K[t] \) with nilpotent kernels and the transition maps \( A_i \to A_j \) are surjective with nilpotent kernels as well. Recall that \( V_i \) is free over \( K \) with basis given by \( s \in S_i \). Then, if the characteristic of \( K \) is zero, the degree \( d \) part of \( A_i \) is free over \( K \) with basis given by \( s^d \), \( s \in S_i \) each of which map to \( t^d \). Hence the inverse system of the degree \( d \) parts of the \( A_i \) is isomorphic to the inverse system of the vector spaces \( V_i \). As \( \lim V_i = 0 \) we conclude that \( \lim A_i = K \), at least when the characteristic of \( K \) is zero. This gives an example of a affine formal algebraic space whose “regular functions” do not separate points.

### 63. Flat maps are not directed limits of finitely presented flat maps

The goal of this section is to give an example of a flat ring map which is not a filtered colimit of flat and finitely presented ring maps. In \([\text{Gab96}]\) it is shown that if \( A \) is a nonexcellent local ring of dimension 1 and residue characteristic zero, then the (flat) ring map \( A \to A^\wedge \) to its completion is not a filtered colimit of finite
type flat ring maps. The example in this section will have a source which is an excellent ring. We encourage the reader to submit other examples; please email stacks.project@gmail.com if you have one.

For the construction, fix a prime $p$, and let $A = \mathbb{F}_p[x_1, \ldots, x_n]$. Choose an absolute integral closure $A^+$ of $A$, i.e., $A^+$ is the integral closure of $A$ in an algebraic closure of its fraction field. In [Hart92, §6.7] it is shown that $A \to A^+$ is flat.

We claim that the $A$-algebra $A^+$ is not a filtered colimit of finitely presented flat $A$-algebras if $n \geq 3$.

We sketch the argument in the case $n = 3$, and we leave the generalization to higher $n$ to the reader. It is enough to prove the analogous statement for the map $R \to R^+$, where $R$ is the strict henselization of $A$ at the origin and $R^+$ is its absolute integral closure. Observe that $R$ is a henselian regular local ring whose residue field $k$ is an algebraic closure of $\mathbb{F}_p$.

Choose an ordinary abelian surface $X$ over $k$ and a very ample line bundle $L$ on $X$. The section ring $\Gamma_+(X, L) = \bigoplus_n H^0(X, L^n)$ is the coordinate ring of the affine cone over $X$ with respect to $L$. It is a normal ring for $L$ sufficiently positive. Let $S$ denote the henselization of $\Gamma_+(X, L)$ at vertex of the cone. Then $S$ is a henselian noetherian normal domain of dimension 3. We obtain a finite injective map $R \to S$ as the henselization of a Noether normalization for the finite type $k$-algebra $\Gamma_+(X, L)$. As $R^+$ is an absolute integral closure of $R$, we can also fix an embedding $S \to R^+$. Thus $R^+$ is also the absolute integral closure of $S$. To show $R^+$ is not a filtered colimit of flat $R$-algebras, it suffices to show:

1. If there exists a factorization $S \to P \to R^+$ with $P$ flat and finite type over $R$, then there exists a factorization $S \to T \to R^+$ with $T$ finite flat over $R$.
2. For any factorization $S \to T \to R^+$ with $S \to T$ finite, the ring $T$ is not $R$-flat.

Indeed, since $S$ is finitely presented over $R$, if one could write $R^+ = \text{colim}_i P_i$ as a filtered colimit of finitely presented flat $R$-algebras $P_i$, then $S \to R^+$ would factor as $S \to P_i \to R^+$ for $i \gg 0$, which contradicts the above pair of assertions. Assertion (1) follows from the fact that $R$ is henselian and a slicing argument, see More on Morphisms, Lemma 18.5. Part (2) was proven in §18.5. For the convenience of the reader, we recall the argument.

Let $U \subset \text{Spec}(S)$ be the punctured spectrum, so there are natural maps $X \leftarrow U \subset \text{Spec}(S)$. The first map gives an identification $H^1(U, \mathcal{O}_U) \simeq H^1(X, \mathcal{O}_X)$. By passing to the Witt vectors of the perfection and using the Artin-Schreier sequence,

\[ \begin{aligned} H^1_{\text{etale}}(U, \mathbb{Z}_p) &\simeq H^1_{\text{etale}}(X, \mathbb{Z}_p), \\
\text{this gives an identification } H^1_{\text{etale}}(U, \mathbb{Z}_p) &\simeq H^1_{\text{etale}}(X, \mathbb{Z}_p). \end{aligned} \]

In particular, this group is a finite free $\mathbb{Z}_p$-module of rank 2 (since $X$ is ordinary). To get a contradiction assume there exists an $R$-flat $T$ as in (2) above. Let $V \subset \text{Spec}(T)$ denote the preimage of $U$, and write $f : V \to U$ for the induced finite surjective map. Since $U$ is normal, there is a trace map $f_*\mathbb{Z}_p \to \mathbb{Z}_p$ on $\mathcal{U}_{\text{etale}}$ whose composition with the pullback $\mathbb{Z}_p \to f_*\mathbb{Z}_p$ is multiplication by $d = \deg(f)$. Passing to cohomology, and using that $H^1_{\text{etale}}(U, \mathbb{Z}_p)$ is nontrivial, then shows that $H^1_{\text{etale}}(V, \mathbb{Z}_p)$ is nonzero. Since $H^1_{\text{etale}}(V, \mathbb{Z}_p) \simeq \text{lim } H^1_{\text{etale}}(V, \mathbb{Z}/p^n)$ as there is no $R^1\text{lim}$ interference, the

\[ \begin{aligned} H^1_{\text{etale}}(U, \mathbb{Z}/p^n) &\simeq \text{kernel of the map } H^1(U, \mathcal{O}_U) \to H^1(U, \mathcal{O}_U) \text{ induced by } f \mapsto f^p - f. \end{aligned} \]
group \( H^1(V_{\text{étale}}, \mathbb{Z}/p) \) must be non-zero. Since \( T \) is \( R \)-flat we have \( \Gamma(V, \mathcal{O}_V) = T \) which is strictly henselian and the Artin-Schreier sequence shows \( H^1(V, \mathcal{O}_V) \neq 0 \). This is equivalent to \( H^2_m(T) \neq 0 \), where \( m \subset R \) is the maximal ideal. Thus, we obtain a contradiction since \( T \) is finite flat (i.e., finite free) as an \( R \)-module and \( H^2_m(R) = 0 \). This contradiction proves (2).

**Lemma 63.1.** There exists a commutative ring \( A \) and a flat \( A \)-algebra \( B \) which cannot be written as a filtered colimit of finitely presented flat \( A \)-algebras. In fact, we may either choose \( A \) to be a finite type \( \mathbb{F}_p \)-algebra or a 1-dimensional Noetherian local ring with residue field of characteristic 0.

**Proof.** See discussion above. \( \square \)

### 64. The category of modules modulo torsion modules

The category of torsion groups is a Serre subcategory (Homology, Definition 9.1) of the category of all abelian groups. More generally, for any ring \( A \), the category of torsion \( A \)-modules is a Serre subcategory of the category of all \( A \)-modules, see More on Algebra, Section 42. If \( A \) is a domain, then the quotient category (Homology, Lemma 9.6) is equivalent to the category of vector spaces over the fraction field.

**Proposition 64.1.** Let \( A \) be an integral domain. Let \( K \) denote its field of fractions. Let \( \text{Mod}_A \) denote the category of \( A \)-modules and \( T \) its Serre subcategory of torsion modules. Let \( \text{Vect}_K \) denote the category of \( K \)-vector spaces. Then there is a canonical equivalence \( \text{Mod}_A/T \rightarrow \text{Vect}_K \).

**Proof.** The functor \( \text{Mod}_A \rightarrow \text{Vect}_K \) given by \( \mathcal{M} \mapsto M \otimes_A K \) is exact (by Algebra, Proposition 9.12) and maps torsion modules to zero. Thus, by the universal property given in Homology, Lemma 9.6 the functor descends to a functor \( \text{Mod}_A/T \rightarrow \text{Vect}_K \).

Conversely, any \( A \)-module \( M \) with \( M \otimes_A K = 0 \) is torsion, since \( M \otimes_A K \cong M[S^{-1}], \) where \( S \subset A \) is the set of regular elements (Algebra, Lemma 11.15). Thus Homology, Lemma 9.7 shows that the functor \( \text{Mod}_A/T \rightarrow \text{Vect}_K \) is faithful.

Furthermore, this embedding is essentially surjective: a preimage to \( K^{(i)} \) is \( A^{(i)} \). To show that the embedding is full, we only have to show that it is full for free modules, since any object in \( \text{Mod}_A/T \) is the cokernel of a morphism between free modules.

Thus let a \( K \)-linear map \( K^{(i)} \rightarrow K^{(j)} \) be given. We can decompose this map into a scaling map \( K^{(i)} \rightarrow K^{(j)}, e_i \mapsto d_i^{-1}e_j \) (\( d_i \in A \)), followed by a map \( K^{(i)} \rightarrow K^{(j)} \) whose (possibly infinite) matrix has all entries in \( A \). It is then obvious that the second map is induced by an \( A \)-linear map \( A^{(i)} \rightarrow A^{(j)} \). The scaling map possesses a preimage in \( \text{Mod}_A/T \) as well, for it is the inverse to the map \( A^{(j)} \rightarrow A^{(i)}, e_j \mapsto d_i \), in \( \text{Mod}_A/T \). This map is indeed invertible in \( \text{Mod}_A/T \), since its kernel is zero (even before passing to the quotient) and its cokernel is a torsion module. \( \square \)

**Proposition 64.2.** Let \( A \) be a Noetherian integral domain. Let \( K \) denote its field of fractions. Let \( \text{Mod}^{fg}_A \) denote the category of finitely generated \( A \)-modules and \( T^{fg} \) its Serre subcategory of finitely generated torsion modules. Then \( \text{Mod}^{fg}_A/T^{fg} \) is canonically equivalent to the category of finite dimensional \( K \)-vector spaces.
Proof. The equivalence given in Proposition 64.1 restricts along the embedding \( \text{Mod}_{\mathcal{A}}^f / T^f \rightarrow \text{Mod}_{\mathcal{A}} / T \) to an equivalence \( \text{Mod}_{\mathcal{A}}^f / T^f \rightarrow \text{Vect}_{\mathcal{K}}^f \). The Noetherian assumption guarantees that \( \text{Mod}_{\mathcal{A}}^f \) is an abelian category (see More on Algebra, Section 42) and that the canonical functor \( \text{Mod}_{\mathcal{A}}^f / T^f \rightarrow \text{Mod}_{\mathcal{A}} / T \) is full (else torsion submodules of finitely generated modules might not be objects of \( T^f \)). □

Proposition 64.3. The quotient of the category of abelian groups modulo its Serre subcategory of torsion groups is the category of \( \mathbb{Q} \)-vector spaces.

Proof. The claim follows directly from Proposition 64.1. □

65. Different colimit topologies

This example is [TSH98, Example 1.2, page 553]. Let \( G_n = \mathbb{Q} \times \mathbb{R}^n, n \geq 1 \) seen as a topological group for addition endowed with the usual (Euclidean) topology. Consider the closed embeddings \( G_n \rightarrow G_{n+1} \) mapping \((x_0, \ldots, x_n)\) to \((x_0, \ldots, x_n, 0)\).

We claim that \( G = \text{colim} G_n \) endowed with the topology \( U \subset G \) open if and only if \( G_n \cap U \) open for all \( n \) is not a topological group.

To see this we consider the set
\[
U = \{(x_0, x_1, x_2, \ldots) \text{ such that } |x_j| < |\cos(jx_0)| \text{ for } j > 0\}
\]
Using that \( jx_0 \) is never an integral multiple of \( \pi/2 \) as \( \pi \) is not rational it is easy to show that \( U \cap G_n \) is open. Since \( 0 \in U \), if the topology above made \( G \) into a topological group, then there would be an open neighbourhood \( V \subset G \) of 0 such that \( V + v \subset U \). Then, for every \( j \geq 0 \) there would exist \( \epsilon_j > 0 \) such that \((0, \ldots, 0, x_j, 0, \ldots) \in V \) for \( |x_j| < \epsilon_j \). Since \( V + V \subset U \) we would have
\[
(x_0, 0, \ldots, 0, x_j, 0, \ldots) \in U
\]
for \( |x_0| < \epsilon_0 \) and \( |x_j| < \epsilon_j \). However, if we take \( j \) large enough such that \( j\epsilon_0 > \pi/2 \), then we can choose \( x_0 \in \mathbb{Q} \) such that \( |\cos(jx_0)| \) is smaller than \( \epsilon_j \), hence there exists an \( x_j \) with \( |\cos(jx_0)| < |x_j| < \epsilon_j \). This contradiction proves the claim.

Lemma 65.1. There exists a system \( G_1 \rightarrow G_2 \rightarrow G_3 \rightarrow \ldots \) of (abelian) topological groups such that \( \text{colim} G_n \) taken in the category of topological spaces is different from \( \text{colim} G_n \) taken in the category of topological groups.

Proof. See discussion above. □
