1. Introduction

This chapter is devoted to generalities concerning groupoid schemes. See for example the beautiful paper [KM97] by Keel and Mori.

2. Notation

Let $S$ be a scheme. If $U$, $T$ are schemes over $S$ we denote $U(T)$ for the set of $T$-valued points of $U$ over $S$. In a formula: $U(T) = Mor_S(T, U)$. We try to reserve
the letter $T$ to denote a “test scheme” over $S$, as in the discussion that follows. Suppose we are given schemes $X, Y$ over $S$ and a morphism of schemes $f : X \to Y$ over $S$. For any scheme $T$ over $S$ we get an induced map of sets

$$f : X(T) \to Y(T)$$

which as indicated we denote by $f$ also. In fact this construction is functorial in the scheme $T/S$. Yoneda’s Lemma, see Categories, Lemma 3.5, says that $f$ determines and is determined by this transformation of functors $f : h_X \to h_Y$. More generally, we use the same notation for maps between fibre products. For example, if $X, Y, Z$ are schemes over $S$, and if $m : X \times_S Y \to Z \times_S Z$ is a morphism of schemes over $S$, then we think of $m$ as corresponding to a collection of maps between $T$-valued points

$$X(T) \times Y(T) \to Z(T) \times Z(T).$$

And so on and so forth.

We continue our convention to label projection maps starting with index 0, so we have $\text{pr}_0 : X \times_S Y \to X$ and $\text{pr}_1 : X \times_S Y \to Y$.

3. Equivalence relations

022O Recall that a relation $R$ on a set $A$ is just a subset of $R \subset A \times A$. We usually write $aRb$ to indicate $(a, b) \in R$. We say the relation is transitive if $aRb, bRc \Rightarrow aRc$. We say the relation is reflexive if $aRa$ for all $a \in A$. We say the relation is symmetric if $aRb \Rightarrow bRa$. A relation is called an equivalence relation if it is transitive, reflexive and symmetric.

In the setting of schemes we are going to relax the notion of a relation a little bit and just require $R \to A \times A$ to be a map. Here is the definition.

022P **Definition 3.1.** Let $S$ be a scheme. Let $U$ be a scheme over $S$.

1. A pre-relation on $U$ over $S$ is any morphism of schemes $j : R \to U \times_S U$.
   In this case we set $t = \text{pr}_0 \circ j$ and $s = \text{pr}_1 \circ j$, so that $j = (t, s)$.
2. A relation on $U$ over $S$ is a monomorphism of schemes $j : R \to U \times_S U$.
3. A pre-equivalence relation is a pre-relation $j : R \to U \times_S U$ such that the image of $j : R(T) \to U(T) \times U(T)$ is an equivalence relation for all $T/S$.
4. We say a morphism $R \to U \times_S U$ of schemes is an equivalence relation on $U$ over $S$ if and only if for every scheme $T$ over $S$ the $T$-valued points of $R$ define an equivalence relation on the set of $T$-valued points of $U$.

In other words, an equivalence relation is a pre-equivalence relation such that $j$ is a relation.

02V8 **Lemma 3.2.** Let $S$ be a scheme. Let $U$ be a scheme over $S$. Let $j : R \to U \times_S U$ be a pre-relation. Let $g : U' \to U$ be a morphism of schemes. Finally, set

$$R' = (U' \times_S U') \times_{U \times_S U} R \to U' \times_S U'$$

Then $j'$ is a pre-relation on $U'$ over $S$. If $j$ is a relation, then $j'$ is a relation. If $j$ is a pre-equivalence relation, then $j'$ is a pre-equivalence relation. If $j$ is an equivalence relation, then $j'$ is an equivalence relation.

**Proof.** Omitted.
**Definition 3.3.** Let $S$ be a scheme. Let $U$ be a scheme over $S$. Let $j : R \to U \times_S U$ be a pre-relation. Let $g : U' \to U$ be a morphism of schemes. The pre-relation $j' : R' \to U' \times_S U'$ is called the restriction, or pullback of the pre-relation $j$ to $U'$. In this situation we sometimes write $R' = R|_{U'}$.

**Lemma 3.4.** Let $j : R \to U \times_S U$ be a pre-relation. Consider the relation on points of the scheme $U$ defined by the rule

$$x \sim y \iff \exists r \in R : t(r) = x, s(r) = y.$$ 

If $j$ is a pre-equivalence relation then this is an equivalence relation.

**Proof.** Suppose that $x \sim y$ and $y \sim z$. Pick $r \in R$ with $t(r) = x$, $s(r) = y$ and pick $r' \in R$ with $t(r') = y$, $s(r') = z$. Pick a field $K$ fitting into the following commutative diagram

![Diagram](https://via.placeholder.com/150)

Denote $x_K, y_K, z_K : \text{Spec}(K) \to U$ the morphisms

- $\text{Spec}(K) \to \text{Spec}(\kappa(r)) \to \text{Spec}(\kappa(x)) \to U$
- $\text{Spec}(K) \to \text{Spec}(\kappa(r)) \to \text{Spec}(\kappa(y)) \to U$
- $\text{Spec}(K) \to \text{Spec}(\kappa(r')) \to \text{Spec}(\kappa(z)) \to U$

By construction $(x_K, y_K) \in j(R(K))$ and $(y_K, z_K) \in j(R(K))$. Since $j$ is a pre-equivalence relation we see that also $(x_K, z_K) \in j(R(K))$. This clearly implies that $x \sim z$.

The proof that $\sim$ is reflexive and symmetric is omitted. □

**Lemma 3.5.** Let $j : R \to U \times_S U$ be a pre-relation. Assume

1. $s, t$ are unramified,
2. for any algebraically closed field $k$ over $S$ the map $R(k) \to U(k) \times U(k)$ is an equivalence relation,
3. there are morphisms $e : U \to R$, $i : R \to R$, $c : R \times_{s,t} R \to R$ such that

![Diagram](https://via.placeholder.com/150)

are commutative.

Then $j$ is an equivalence relation.

**Proof.** By condition (1) and Morphisms, Lemma [33.16] we see that $j$ is a unramified. Then $\Delta_j : R \to R \times_{U \times_S U} R$ is an open immersion by Morphisms, Lemma [33.13]. However, then condition (2) says $\Delta_j$ is bijective on $k$-valued points, hence $\Delta_j$ is an isomorphism, hence $j$ is a monomorphism. Then it easily follows from the commutative diagrams that $R(T) \subset U(T) \times U(T)$ is an equivalence relation for all schemes $T$ over $S$. □
4. Group schemes

Let us recall that a group is a pair \((G, m)\) where \(G\) is a set, and \(m : G \times G \to G\) is a map of sets with the following properties:

1. (associativity) \(m(g, m(g', g'')) = m(m(g, g'), g'')\) for all \(g, g', g'' \in G\).
2. (identity) there exists a unique element \(e \in G\) (called the identity, unit, or 1 of \(G\)) such that \(m(g, e) = m(e, g) = g\) for all \(g \in G\), and
3. (inverse) for all \(g \in G\) there exists a \(i(g) \in G\) such that \(m(g, i(g)) = m(i(g), g) = e\), where \(e\) is the identity.

Thus we obtain a map \(e : \{\ast\} \to G\) and a map \(i : G \to G\) so that the quadruple \((G, m, e, i)\) satisfies the axioms listed above.

A homomorphism of groups \(\psi : (G, m) \to (G', m')\) is a map of sets \(\psi : G \to G'\) such that \(m'(\psi(g), \psi(g')) = \psi(m(g, g'))\). This automatically insures that \(\psi(e) = e'\) and \(\psi(i(g)) = i'(g)\). (Obvious notation.) We will use this below.

Definition 4.1. Let \(S\) be a scheme.

1. A group scheme over \(S\) is a pair \((G, m)\), where \(G\) is a scheme over \(S\) and \(m : G \times_S G \to G\) is a morphism of schemes over \(S\) with the following property: For every scheme \(T\) over \(S\) the pair \((G(T), m)\) is a group.
2. A morphism \(\psi : (G, m) \to (G', m')\) of group schemes over \(S\) is a morphism \(\psi : G \to G'\) of schemes over \(S\) such that for every \(T/S\) the induced map \(\psi : G(T) \to G'(T)\) is a homomorphism of groups.

Let \((G, m)\) be a group scheme over the scheme \(S\). By the discussion above (and the discussion in Section \[2\]) we obtain morphisms of schemes over \(S\): (identity) \(e : S \to G\) and (inverse) \(i : G \to G\) such that for every \(T\) the quadruple \((G(T), m, e, i)\) satisfies the axioms of a group listed above.

Let \((G, m)\), \((G', m')\) be group schemes over \(S\). Let \(f : G \to G'\) be a morphism of schemes over \(S\). It follows from the definition that \(f\) is a morphism of group schemes over \(S\) if and only if the following diagram is commutative:

\[
\begin{array}{ccc}
G \times_S G & \xrightarrow{f \times f} & G' \times_S G' \\
m \downarrow & & \downarrow m \\
G & \xrightarrow{f} & G'
\end{array}
\]

Lemma 4.2. Let \((G, m)\) be a group scheme over \(S\). Let \(S' \to S\) be a morphism of schemes. The pullback \((G_{S'}, m_{S'})\) is a group scheme over \(S'\).

Proof. Omitted.

Definition 4.3. Let \(S\) be a scheme. Let \((G, m)\) be a group scheme over \(S\).

1. A closed subgroup scheme of \(G\) is a closed subscheme \(H \subset G\) such that \(m|_{H \times H}\) factors through \(H\) and induces a group scheme structure on \(H\) over \(S\).
2. An open subgroup scheme of \(G\) is an open subscheme \(G' \subset G\) such that \(m|_{G' \times G'}\) factors through \(G'\) and induces a group scheme structure on \(G'\) over \(S\).

Alternatively, we could say that \(H\) is a closed subgroup scheme of \(G\) if it is a group scheme over \(S\) endowed with a morphism of group schemes \(i : H \to G\) over \(S\) which identifies \(H\) with a closed subscheme of \(G\).
Definition 4.4. Let $S$ be a scheme. Let $(G, m)$ be a group scheme over $S$.

1. We say $G$ is a smooth group scheme if the structure morphism $G \to S$ is smooth.
2. We say $G$ is a flat group scheme if the structure morphism $G \to S$ is flat.
3. We say $G$ is a separated group scheme if the structure morphism $G \to S$ is separated.

Add more as needed.

5. Examples of group schemes

Example 5.1 (Multiplicative group scheme). Consider the functor which associates to any scheme $T$ the group $\Gamma(T, \mathcal{O}_T^*)$ of units in the global sections of the structure sheaf. This is representable by the scheme $G_m = \text{Spec}(\mathbb{Z}[x, x^{-1}])$

The morphism giving the group structure is the morphism

$$G_m \times G_m \to G_m$$

$$\text{Spec}(\mathbb{Z}[x, x^{-1}] \otimes_{\mathbb{Z}} \mathbb{Z}[x, x^{-1}]) \to \text{Spec}(\mathbb{Z}[x, x^{-1}])$$

$$\mathbb{Z}[x, x^{-1}] \otimes_{\mathbb{Z}} \mathbb{Z}[x, x^{-1}] \leftarrow \mathbb{Z}[x, x^{-1}]$$

$$x \otimes x \leftarrow x$$

Hence we see that $G_m$ is a group scheme over $\mathbb{Z}$. For any scheme $S$ the base change $G_{m,S}$ is a group scheme over $S$ whose functor of points is

$$T/S \mapsto G_{m,S}(T) = G_m(T) = \Gamma(T, \mathcal{O}_T^*)$$

as before.

Example 5.2 (Roots of unity). Let $n \in \mathbb{N}$. Consider the functor which associates to any scheme $T$ the subgroup of $\Gamma(T, \mathcal{O}_T^*)$ consisting of $n$th roots of unity. This is representable by the scheme

$$\mu_n = \text{Spec}(\mathbb{Z}[x]/(x^n - 1))$$

The morphism giving the group structure is the morphism

$$\mu_n \times \mu_n \to \mu_n$$

$$\text{Spec}(\mathbb{Z}[x]/(x^n - 1) \otimes_{\mathbb{Z}} \mathbb{Z}[x]/(x^n - 1)) \to \text{Spec}(\mathbb{Z}[x]/(x^n - 1))$$

$$\mathbb{Z}[x]/(x^n - 1) \otimes_{\mathbb{Z}} \mathbb{Z}[x]/(x^n - 1) \leftarrow \mathbb{Z}[x]/(x^n - 1)$$

$$x \otimes x \leftarrow x$$

Hence we see that $\mu_n$ is a group scheme over $\mathbb{Z}$. For any scheme $S$ the base change $\mu_{n,S}$ is a group scheme over $S$ whose functor of points is

$$T/S \mapsto \mu_{n,S}(T) = \mu_n(T) = \{ f \in \Gamma(T, \mathcal{O}_T^*) \mid f^n = 1 \}$$

as before.

Example 5.3 (Additive group scheme). Consider the functor which associates to any scheme $T$ the group $\Gamma(T, \mathcal{O}_T)$ of global sections of the structure sheaf. This is representable by the scheme

$$G_a = \text{Spec}(\mathbb{Z}[x])$$
The morphism giving the group structure is the morphism

\[
\mathbb{G}_a \times \mathbb{G}_a \rightarrow \mathbb{G}_a
\]

\[
\text{Spec}(\mathbb{Z}[x] \otimes_{\mathbb{Z}} \mathbb{Z}[x]) \rightarrow \text{Spec}(\mathbb{Z}[x])
\]

\[
\mathbb{Z}[x] \otimes_{\mathbb{Z}} \mathbb{Z}[x] \leftarrow \mathbb{Z}[x]
\]

\[
x \otimes 1 + 1 \otimes x \leftarrow x
\]

Hence we see that \(\mathbb{G}_a\) is a group scheme over \(\mathbb{Z}\). For any scheme \(S\) the base change \(\mathbb{G}_{a,S}\) is a group scheme over \(S\) whose functor of points is

\[
T/S \mapsto \mathbb{G}_{a,S}(T) = \mathbb{G}_a(T) = \Gamma(T, \mathcal{O}_T)
\]

as before.

**Example 5.4** (General linear group scheme). Let \(n \geq 1\). Consider the functor which associates to any scheme \(T\) the group

\[\text{GL}_n(\Gamma(T, \mathcal{O}_T))\]

of invertible \(n \times n\) matrices over the global sections of the structure sheaf. This is representable by the scheme

\[\text{GL}_n = \text{Spec}(\mathbb{Z}[[x_{ij}]_{1 \leq i,j \leq n}[1/d]])\]

where \(d = \text{det}((x_{ij}))\) with \((x_{ij})\) the \(n \times n\) matrix with entry \(x_{ij}\) in the \((i,j)\)-spot. The morphism giving the group structure is the morphism

\[
\text{GL}_n \times \text{GL}_n \rightarrow \text{GL}_n
\]

\[
\text{Spec}(\mathbb{Z}[x_{ij}, 1/d] \otimes_{\mathbb{Z}} \mathbb{Z}[x_{ij}, 1/d]) \rightarrow \text{Spec}(\mathbb{Z}[x_{ij}, 1/d])
\]

\[
\mathbb{Z}[x_{ij}, 1/d] \otimes_{\mathbb{Z}} \mathbb{Z}[x_{ij}, 1/d] \leftarrow \mathbb{Z}[x_{ij}, 1/d]
\]

\[
\sum_{k=1}^n x_{ik} \otimes x_{kj} \leftarrow x_{ij}
\]

Hence we see that \(\text{GL}_n\) is a group scheme over \(\mathbb{Z}\). For any scheme \(S\) the base change \(\text{GL}_{n,S}\) is a group scheme over \(S\) whose functor of points is

\[
T/S \mapsto \text{GL}_{n,S}(T) = \text{GL}_n(T) = \text{GL}_n(\Gamma(T, \mathcal{O}_T))
\]

as before.

**Example 5.5.** The determinant defines a morphism of group schemes

\[\text{det} : \text{GL}_n \rightarrow \mathbb{G}_m\]

over \(\mathbb{Z}\). By base change it gives a morphism of group schemes \(\text{GL}_{n,S} \rightarrow \mathbb{G}_{m,S}\) over any base scheme \(S\).

**Example 5.6** (Constant group). Let \(G\) be an abstract group. Consider the functor which associates to any scheme \(T\) the group of locally constant maps \(T \rightarrow G\) (where \(T\) has the Zariski topology and \(G\) the discrete topology). This is representable by the scheme

\[G_{\text{Spec}(\mathbb{Z})} = \prod_{g \in G} \text{Spec}(\mathbb{Z}).\]

The morphism giving the group structure is the morphism

\[G_{\text{Spec}(\mathbb{Z})} \times_{\text{Spec}(\mathbb{Z})} G_{\text{Spec}(\mathbb{Z})} \rightarrow G_{\text{Spec}(\mathbb{Z})}\]
which maps the component corresponding to the pair \((g,g')\) to the component corresponding to \(gg'\). For any scheme \(S\) the base change \(G_S\) is a group scheme over \(S\) whose functor of points is
\[
T/S \mapsto G_S(T) = \{f : T \to G \text{ locally constant}\}
\]
as before.

6. Properties of group schemes

In this section we collect some simple properties of group schemes which hold over any base.

**Lemma 6.1.** Let \(S\) be a scheme. Let \(G\) be a group scheme over \(S\). Then \(G \to S\) is separated (resp. quasi-separated) if and only if the identity morphism \(e : S \to G\) is a closed immersion (resp. quasi-compact).

**Proof.** We recall that by Schemes, Lemma [21.11] we have that \(e\) is an immersion which is a closed immersion (resp. quasi-compact) if \(G \to S\) is separated (resp. quasi-separated). For the converse, consider the diagram
\[
\begin{array}{ccc}
G & \xrightarrow{\Delta_{G/S}} & G \\
\downarrow & & \downarrow \\
S & \xrightarrow{e} & G \\
\end{array}
\]
It is an exercise in the functorial point of view in algebraic geometry to show that this diagram is cartesian. In other words, we see that \(\Delta_{G/S}\) is a base change of \(e\). Hence if \(e\) is a closed immersion (resp. quasi-compact) so is \(\Delta_{G/S}\), see Schemes, Lemma [18.2] (resp. Schemes, Lemma [19.3]).

**Lemma 6.2.** Let \(S\) be a scheme. Let \(G\) be a group scheme over \(S\). Let \(T\) be a scheme over \(S\) and let \(\psi : T \to G\) be a morphism over \(S\). If \(T\) is flat over \(S\), then the morphism
\[
T \times_S G \to G, \quad (t,g) \mapsto m(\psi(t),g)
\]
is flat. In particular, if \(G\) is flat over \(S\), then \(m : G \times_S G \to G\) is flat.

**Proof.** Consider the diagram
\[
\begin{array}{ccc}
T \times_S G & \xrightarrow{(t,g) \mapsto (t,m(\psi(t),g))} & T \times_S G \\
\downarrow & & \downarrow \\
T & \xrightarrow{\text{pr}} & G \\
\end{array}
\]
The left top horizontal arrow is an isomorphism and the square is cartesian. Hence the lemma follows from Morphisms, Lemma [24.7].

**Lemma 6.3.** Let \((G,m,e,i)\) be a group scheme over the scheme \(S\). Denote \(f : G \to S\) the structure morphism. Assume \(f\) is flat. Then there exist canonical isomorphisms
\[
\Omega_{G/S} \cong f^*\mathcal{C}_{S/G} \cong f^*e^*\Omega_{G/S}
\]
where \(\mathcal{C}_{S/G}\) denotes the conormal sheaf of the immersion \(e\). In particular, if \(S\) is the spectrum of a field, then \(\Omega_{G/S}\) is a free \(\mathcal{O}_G\)-module.
In this section we collect some properties of group schemes over a field. In the case $T \times \xi$, Lemma 22.4). Every point of $T \times_k U$ is is open. Combining these facts we see that the image of $T \times_k U \to G$ contains an open neighbourhood of the image of $\xi$. Since $\xi$ was arbitrary we win.

**Lemma 7.1.** If $(G, m)$ is a group scheme over a field $k$, then the multiplication map $m : G \times_k G \to G$ is open.

**Proof.** The multiplication map is isomorphic to the projection map $pr_0 : G \times_k G \to G$ because the diagram

$$
\begin{array}{ccc}
G \times_k G & \xrightarrow{(g,g') \mapsto (m(g,g'),g')} & G \times_k G \\
\downarrow m & & \downarrow (g,g') \mapsto g \\
G & \xrightarrow{id} & G
\end{array}
$$

is commutative with isomorphisms as horizontal arrows. The projection is open by Morphisms, Lemma 22.4.

**Lemma 7.2.** If $(G, m)$ is a group scheme over a field $k$. Let $U \subset G$ open and $T \to G$ a morphism of schemes. Then the image of the composition $T \times_k U \to G \times_k G \to G$ is open.

**Proof.** For any field extension $k \subset K$ the morphism $G_K \to G$ is open (Morphisms, Lemma 22.4). Every point $\xi$ of $T \times_k U$ is the image of a morphism $(t, u) : \text{Spec}(K) \to T \times_k U$ for some $K$. Then the image of $T_K \times_K U_K = (T \times_k U)_K \to G_K$ contains the translate $t \cdot U_K$ which is open. Combining these facts we see that the image of $T \times_k U \to G$ contains an open neighbourhood of the image of $\xi$. Since $\xi$ was arbitrary we win.

**Lemma 7.3.** Let $G$ be a group scheme over a field. Then $G$ is a separated scheme.
047M \textbf{Lemma 7.4.} Let $G$ be a group scheme over a field $k$. Then

1. every local ring $O_{G,g}$ of $G$ has a unique minimal prime ideal,
2. there is exactly one irreducible component $Z$ of $G$ passing through $e$, and
3. $Z$ is geometrically irreducible over $k$.

\textbf{Proof.} For any point $g \in G$ there exists a field extension $k \subset K$ and a $K$-valued point $g' \in G(K)$ mapping to $g$. If we think of $g'$ as a $K$-rational point of the group scheme $G_K$, then we see that $O_{G,g} \to O_{G_K,g'}$ is a faithfully flat local ring map (as $G_K \to G$ is flat, and a local flat ring map is faithfully flat, see Algebra, Lemma \ref{cite}). The result for $O_{G_K,g'}$ implies the result for $O_{G,g}$, see Algebra, Lemma \ref{cite}.

Hence in order to prove (1) it suffices to prove it for $k$-rational points $g$ of $G$. In this case translation by $g$ defines an automorphism $G \to G$ which maps $e$ to $g$. Hence $O_{G,g} \cong O_{G,e}$. In this way we see that (2) implies (1), since irreducible components passing through $e$ correspond one to one with minimal prime ideals of $O_{G,e}$.

In order to prove (2) and (3) it suffices to prove (2) when $k$ is algebraically closed. In this case, let $Z_1, Z_2$ be two irreducible components of $G$ passing through $e$. Since $k$ is algebraically closed the closed subscheme $Z_1 \times_k Z_2 \subset G \times_k G$ is irreducible too, see Varieties, Lemma \ref{cite}. Hence $m(Z_1 \times_k Z_2)$ is contained in an irreducible component of $G$. On the other hand it contains $Z_1$ and $Z_2$ since $m|_{e \times G} = \text{id}_G$ and $m|_{G \times e} = \text{id}_G$. We conclude $Z_1 = Z_2$ as desired. \hfill \bbox

04L9 \textbf{Remark 7.5.} Warning: The result of Lemma \ref{cite} does not mean that every irreducible component of $G/k$ is geometrically irreducible. For example the group scheme $\mu_3, Q = \text{Spec}(Q[x]/(x^3 - 1))$ over $Q$ has two irreducible components corresponding to the factorization $x^3 - 1 = (x - 1)(x^2 + x + 1)$. The first factor corresponds to the irreducible component passing through the identity, and the second irreducible component is not geometrically irreducible over $\text{Spec}(Q)$.

047R \textbf{Lemma 7.6.} Let $G$ be a group scheme over a perfect field $k$. Then the reduction $G_{\text{red}}$ of $G$ is a closed subgroup scheme of $G$.

\textbf{Proof.} Omitted. Hint: Use that $G_{\text{red}} \times_k G_{\text{red}}$ is reduced by Varieties, Lemmas \ref{cite} and \ref{cite}.

047S \textbf{Lemma 7.7.} Let $k$ be a field. Let $\psi : G' \to G$ be a morphism of group schemes over $k$. If $\psi(G')$ is open in $G$, then $\psi(G')$ is closed in $G$.

\textbf{Proof.} Let $U = \psi(G') \subset G$. Let $Z = G \setminus \psi(G') = G \setminus U$ with the reduced induced closed subscheme structure. By Lemma \ref{cite} the image of

$Z \times_k G' \longrightarrow Z \times_k U \longrightarrow G$

is open (the first arrow is surjective). On the other hand, since $\psi$ is a homomorphism of group schemes, the image of $Z \times_k G' \to G$ is contained in $Z$ (because translation by $\psi(g')$ preserves $U$ for all points $g'$ of $G'$; small detail omitted). Hence $Z \subset G$ is
an open subset (although not necessarily an open subscheme). Thus $U = \psi(G')$ is closed.

Lemma 7.8. Let $i : G' \to G$ be an immersion of group schemes over a field $k$. Then $i$ is a closed immersion, i.e., $i(G')$ is a closed subgroup scheme of $G$.

Proof. To show that $i$ is a closed immersion it suffices to show that $i(G')$ is a closed subset of $G$. Let $k \subset k'$ be a perfect extension of $k$. If $i(G'_{k'}) \subset G_{k'}$ is closed, then $i(G') \subset G$ is closed by Morphisms, Lemma 24.11 (as $G_{k'} \to G$ is flat, quasi-compact and surjective). Hence we may and do assume $k$ is perfect. We will use without further mention that products of reduced schemes over $k$ are reduced.

We may replace $G'$ and $G$ by their reductions, see Lemma 7.6. Let $G' \subset G$ be the closure of $i(G')$ viewed as a reduced closed subscheme. By Varieties, Lemma 24.1 we conclude that $G' \times_k G'$ is the closure of the image of $G' \times_k G' \to G \times_k G$. Hence $m(G' \times_k G') \subset G'$ as $m$ is continuous. It follows that $G' \subset G$ is a (reduced) closed subgroup scheme. By Lemma 7.7 we see that $i(G') \subset G'$ is also closed which implies that $i(G') = G'$ as desired. □

Lemma 7.9. Let $G$ be a group scheme over a field $k$. If $G$ is irreducible, then $G$ is quasi-compact.

Proof. Suppose that $k \subset K$ is a field extension. If $G_K$ is quasi-compact, then $G$ is too as $G_K \to G$ is surjective. By Lemma 7.4 we see that $G_K$ is irreducible. Hence it suffices to prove the lemma after replacing $k$ by some extension. Choose $K$ to be an algebraically closed field extension of very large cardinality. Then by Varieties, Lemma 14.2 we see that $G_K$ is a Jacobson scheme all of whose closed points have residue field equal to $K$. In other words we may assume $G$ is a Jacobson scheme all of whose closed points have residue field $k$. Let $U \subset G$ be a nonempty affine open. Let $g \in G(k)$. Then $gU \cap U \neq \emptyset$. Hence we see that $g$ is in the image of the morphism

$$U \times_{\text{Spec}(k)} U \longrightarrow G, \quad (u_1, u_2) \longmapsto u_1 u_2^{-1}$$

Since the image of this morphism is open (Lemma 7.4) we see that the image is all of $G$ (because $G$ is Jacobson and closed points are $k$-rational). Since $U$ is affine, so is $U \times_{\text{Spec}(k)} U$. Hence $G$ is the image of a quasi-compact scheme, hence quasi-compact. □

Lemma 7.10. Let $G$ be a group scheme over a field $k$. If $G$ is connected, then $G$ is irreducible.

Proof. By Varieties, Lemma 7.13 we see that $G$ is geometrically connected. If we show that $G_K$ is irreducible for some field extension $k \subset K$, then the lemma follows. Hence we may apply Varieties, Lemma 14.2 to reduce to the case where $k$ is algebraically closed, $G$ is a Jacobson scheme, and all the closed points are $k$-rational.

Let $Z \subset G$ be the unique irreducible component of $G$ passing through the neutral element, see Lemma 7.4. Endowing $Z$ with the reduced induced closed subscheme structure, we see that $Z \times_k Z$ is reduced and irreducible (Varieties, Lemmas 6.7
Let $m|_{Z \times_k Z} : Z \times_k Z \to G$ factors through $Z$. Hence $Z$ becomes a closed subgroup scheme of $G$.

To get a contradiction, assume there exists another irreducible component $Z' \subset G$. Then $Z \cap Z' = \emptyset$ by Lemma 7.4. By Lemma 7.9 we see that $Z$ is quasi-compact. Thus we may choose a quasi-compact open $U \subset G$ with $Z \subset U$ and $U \cap Z' = \emptyset$. The image $W$ of $Z \times_k U \to G$ is open in $G$ by Lemma 7.2. On the other hand, $W$ is quasi-compact as the image of a quasi-compact space. We claim that $W$ is closed. If the claim is true, then $W \subset G \setminus Z'$ is a proper open and closed subset of $G$, which contradicts the assumption that $G$ is connected.

Proof of the claim. Since $W$ is quasi-compact, we see that points in the closure of $W$ are specializations of points of $W$ (Morphisms, Lemma 6.5). Thus we have to show that any irreducible component $Z'' \subset G$ of $G$ which meets $W$ is contained in $W$. As $G$ is Jacobson and closed points are rational, $Z'' \cap W$ has a rational point $g \in Z''(k) \cap W(k)$ and hence $Z'' = Zg$. But $W = m(Z \times_k W)$ by construction, so $Z'' \cap W \neq \emptyset$ implies $Z'' \subset W$. $\square$

**Proposition 7.11.** Let $G$ be a group scheme over a field $k$. There exists a canonical closed subgroup scheme $G^0 \subset G$ with the following properties

1. $G^0 \to G$ is a flat closed immersion,
2. $G^0 \subset G$ is the connected component of the identity,
3. $G^0$ is geometrically irreducible, and
4. $G^0$ is quasi-compact.

**Proof.** Let $G^0$ be the connected component of the identity with its canonical scheme structure (Morphisms, Definition 25.3). By Varieties, Lemma 7.13 we see that $G^0$ is geometrically connected. Thus $G^0 \times_k G^0$ is connected (Varieties, Lemma 7.4). Thus $m(G^0 \times_k G^0) \subset G^0$ set theoretically. To see that this holds scheme theoretically, note that $G^0 \times_k G^0 \to G \times_k G$ is a flat closed immersion. By Morphisms, Lemma 25.1 it follows that $G^0 \times_k G^0$ is a closed subscheme of $(G \times_k G) \times_{m,G} G^0$. Thus we see that $m|_{G^0 \times_k G^0} : G^0 \times_k G^0 \to G$ factors through $G^0$. Hence $G^0$ becomes a closed subgroup scheme of $G$. By Lemma 7.10 we see that $G^0$ is irreducible. By Lemma 7.4 we see that $G^0$ is geometrically irreducible. By Lemma 7.9 we see that $G^0$ is quasi-compact. $\square$

**Lemma 7.12.** Let $k$ be a field. Let $T = \text{Spec}(A)$ where $A$ is a directed colimit of algebras which are finite products of copies of $k$. For any scheme $X$ over $k$ we have $|T \times_k X| = |T| \times |X|$ as topological spaces.

**Proof.** By taking an affine open covering we reduce to the case of an affine $X$. Say $X = \text{Spec}(B)$. Write $A = \text{colim} A_i$ with $A_i = \prod_{T_i \in T_i} k$ and $T_i$ finite. Then $T_i = |\text{Spec}(A_i)|$ with the discrete topology and the transition morphisms $A_i \to A_{i'}$ are given by set maps $T_i \to T_i$. Thus $|T| = \text{lim} T_i$ as a topological space, see
Similarly we have
\[ |T \times_k X| = |\text{Spec}(A \otimes_k B)| \]
\[ = |\text{Spec}(\text{colim} A_\ell \otimes_k B)| \]
\[ = \lim |\text{Spec}(A_\ell \otimes_k B)| \]
\[ = \lim |\text{Spec}(\prod_{i \in I} T_i)| \]
\[ = \lim T_i \times |X| \]
\[ = (\lim T_i) \times |X| \]
\[ = |T| \times |X| \]

by the lemma above and the fact that limits commute with limits.

The following lemma says that in fact we can put a “algebraic profinite family of points” in an affine open. We urge the reader to read Lemma 8.6 first.

Lemma 7.13. Let $k$ be an algebraically closed field. Let $G$ be a group scheme over $k$. Assume that $G$ is Jacobson and that all closed points are $k$-rational. Let $T = \text{Spec}(A)$ where $A$ is a directed colimit of algebras which are finite products of copies of $k$. For any morphism $f : T \to G$ there exists an affine open $U \subset G$ containing $f(T)$.

Proof. Let $G^0 \subset G$ be the closed subgroup scheme found in Proposition 7.11. The first two paragraphs serve to reduce to the case $G = G^0$.

Observe that $T$ is a directed inverse limit of finite topological spaces (Limits, Lemma 4.6), hence profinite as a topological space (Topology, Definition 22.1). Let $W \subset G$ be a quasi-compact open containing the image of $T \to G$. After replacing $W$ by the image of $G^0 \times W \to G \times G \to G$ we may assume that $W$ is invariant under the action of left translation by $G^0$, see Lemma 7.2. Consider the composition

\[ \psi = \pi \circ f : T \xrightarrow{f} W \xrightarrow{\pi_0} \pi_0(W) \]

The space $\pi_0(W)$ is profinite (Topology, Lemma 23.8 and Properties, Lemma 2.4). Let $F_\xi \subset T$ be the fibre of $T \to \pi_0(W)$ over $\xi \in \pi_0(W)$. Assume that for all $\xi$ we can find an affine open $U_\xi \subset W$ with $F \subset U$. Since $\psi : T \to \pi_0(W)$ is proper as a map of topological spaces (Topology, Lemma 17.7), we can find a quasi-compact open $V_\xi \subset \pi_0(W)$ such that $\psi^{-1}(V_\xi) \subset f^{-1}(U_\xi)$ (easy topological argument omitted).

After replacing $U_\xi$ by $U_\xi \cap \pi^{-1}(V_\xi)$, which is open and closed in $U_\xi$ hence affine, we see that $U_\xi \subset \pi^{-1}(V_\xi)$ and $U_\xi \cap T = \psi^{-1}(V_\xi)$. By Topology, Lemma 22.4 we can find a finite disjoint union decomposition $\pi_0(W) = \bigcup_{i=1,...,n} V_i$ by quasi-compact opens such that $V_i \subset V_\xi_i$ for some $i$. Then we see that

\[ f(T) \subset \bigcup_{i=1,...,n} U_\xi_i \cap \pi^{-1}(V_i) \]

the right hand side of which is a finite disjoint union of affines, therefore affine.

Let $Z$ be a connected component of $G$ which meets $f(T)$. Then $Z$ has a $k$-rational point $z$ (because all residue fields of the scheme $T$ are isomorphic to $k$). Hence $Z = G^0 z$. By our choice of $W$, we see that $Z \subset W$. The argument in the preceding paragraph reduces us to the problem of finding an affine open neighbourhood of $f(T) \cap Z$ in $W$. After translation by a rational point we may assume that $Z = G^0$ (details omitted). Observe that the scheme theoretic inverse image $T' = f^{-1}(G^0) \subset$
Let a scheme over a field $G$ be a group scheme over a field, is there always a quasi-compact open and closed subgroup scheme? By Proposition 7.11 this question is only interesting if $G$ has infinitely many connected components (geometrically).

**Remark 7.14.** If $G$ is a group scheme over a field, is there always a quasi-compact open and closed subgroup scheme? By Proposition 7.12 this question is only interesting if $G$ has infinitely many connected components (geometrically).

**Lemma 7.15.** Let $G$ be a group scheme over a field. There exists an open and closed subscheme $G' \subset G$ which is a countable union of affines.

**Proof.** Let $e \in U(k)$ be a quasi-compact open neighbourhood of the identity element. By replacing $U$ by $U \cap i(U)$ we may assume that $U$ is invariant under the inverse map. As $G$ is separated this is still a quasi-compact set. Set

$$G' = \bigcup_{n \geq 1} m_n(U \times_k \ldots \times_k U)$$

where $m_n : G \times_k \ldots \times_k G \to G$ is the $n$-slot multiplication map $(g_1, \ldots, g_n) \mapsto m(m(\ldots(m(g_1, g_2), g_3), \ldots), g_n)$. Each of these maps are open (see Lemma 7.1) hence $G'$ is an open subgroup scheme. By Lemma 7.7 it is also a closed subgroup scheme. □

8. Properties of algebraic group schemes

Recall that a scheme over a field $k$ is (locally) algebraic if it is (locally) of finite type over Spec($k$), see Varieties, Definition 20.1. This is the sense of algebraic we are using in the title of this section.

**Lemma 8.1.** Let $k$ be a field. Let $G$ be a locally algebraic group scheme over $k$. Then $G$ is equidimensional and $\dim(G) = \dim_g(G)$ for all $g \in G$. For any closed point $g \in G$ we have $\dim(G) = \dim(\mathcal{O}_{G,g})$. 

Proof. Let us first prove that \( \dim_g(G) = \dim_{g'}(G) \) for any pair of points \( g, g' \in G \). By Morphisms, Lemma 27.3 we may extend the ground field at will. Hence we may assume that both \( g \) and \( g' \) are defined over \( k \). Hence there exists an automorphism of \( G \) mapping \( g \) to \( g' \), whence the equality. By Morphisms, Lemma 27.1 we have \( \dim_g(G) = \dim(\mathcal{O}_{G,g}) + \text{trdeg}_k(\kappa(g)) \). On the other hand, the dimension of \( G \) (or any open subset of \( G \)) is the supremum of the dimensions of the local rings of \( G \), see Properties, Lemma 10.3. Clearly this is maximal for closed points \( g \) in which case \( \text{trdeg}_k(\kappa(g)) = 0 \) (by the Hilbert Nullstellensatz, see Morphisms, Section 15). Hence the lemma follows. 

The following result is sometimes referred to as Cartier’s theorem.

Lemma 8.2. Let \( k \) be a field of characteristic 0. Let \( G \) be a locally algebraic group scheme over \( k \). Then the structure morphism \( G \to \text{Spec}(k) \) is smooth, i.e., \( G \) is a smooth group scheme.

Proof. By Lemma 6.3 the module of differentials of \( G \) over \( k \) is free. Hence smoothness follows from Varieties, Lemma 25.1.

Remark 8.3. Any group scheme over a field of characteristic 0 is reduced, see [Per75, I, Theorem 1.1 and I, Corollary 3.9, and II, Theorem 2.4] and also [Per76, Proposition 4.2.8]. This was a question raised in [Oor66, page 80]. We have seen in Lemma 8.2 that this holds when the group scheme is locally of finite type.

Lemma 8.4. Let \( k \) be a perfect field of characteristic \( p > 0 \) (see Lemma 8.2 for the characteristic zero case). Let \( G \) be a locally algebraic group scheme over \( k \). If \( G \) is reduced then the structure morphism \( G \to \text{Spec}(k) \) is smooth, i.e., \( G \) is a smooth group scheme.

Proof. By Lemma 6.3 the sheaf \( \Omega_{G/k} \) is free. Hence the lemma follows from Varieties, Lemma 25.2.

Remark 8.5. Let \( k \) be a field of characteristic \( p > 0 \). Let \( \alpha \in k \) be an element which is not a \( p \)th power. The closed subgroup scheme \( G = V(x^p + \alpha y^p) \subset G^2_{a,k} \) is reduced and irreducible but not smooth (not even normal).

The following lemma is a special case of Lemma 7.13 with a somewhat easier proof.

Lemma 8.6. Let \( k \) be an algebraically closed field. Let \( G \) be a locally algebraic group scheme over \( k \). Let \( g_1, \ldots, g_n \in G(k) \) be \( k \)-rational points. Then there exists an affine open \( U \subset G \) containing \( g_1, \ldots, g_n \).

Proof. We first argue by induction on \( n \) that we may assume all \( g_i \) are on the same connected component of \( G \). Namely, if not, then we can find a decomposition \( G = W_1 \amalg W_2 \) with \( W_i \) open in \( G \) and (after possibly renumbering) \( g_1, \ldots, g_r \in W_1 \) and \( g_{r+1}, \ldots, g_n \in W_2 \) for some \( 0 < r < n \). By induction we can find affine opens \( U_1 \) and \( U_2 \) of \( G \) with \( g_1, \ldots, g_r \in U_1 \) and \( g_{r+1}, \ldots, g_n \in U_2 \). Then \( g_1, \ldots, g_n \in (U_1 \cap W_1) \cup (U_2 \cap W_2) \) is a solution to the problem. Thus we may assume \( g_1, \ldots, g_n \) are all on the same connected component of \( G \). Translating by \( g_1^{-1} \) we may assume \( g_1, \ldots, g_n \in G^0 \)
where $G^0 \subset G$ is as in Proposition 7.11. Choose an affine open neighbourhood $U$ of $e$, in particular $U \cap G^0$ is nonempty. Since $G^0$ is irreducible we see that

$$G^0 \cap (Ug_1^{-1} \cap \ldots \cap Ug_n^{-1})$$

is nonempty. Since $G \to \text{Spec}(k)$ is locally of finite type, also $G^0 \to \text{Spec}(k)$ is locally of finite type, hence any nonempty open has a $k$-rational point. Thus we can pick $g \in G^0(k)$ with $g \in Ug_i^{-1}$ for all $i$. Then $g_i \in g_i^{-1}U$ for all $i$ and $g_i^{-1}U$ is the affine open we were looking for.

□

**Lemma 8.7.** Let $k$ be a field. Let $G$ be an algebraic group scheme over $k$. Then $G$ is quasi-projective over $k$.

**Proof.** By Varieties, Lemma 15.1 we may assume that $k$ is algebraically closed. Let $G^0 \subset G$ be the connected component of $G$ as in Proposition 7.11. Then every other connected component of $G$ has a $k$-rational point and hence is isomorphic to $G^0$ as a scheme. Since $G$ is quasi-compact and Noetherian, there are finitely many of these connected components. Thus we reduce to the case discussed in the next paragraph.

Let $G$ be a connected algebraic group scheme over an algebraically closed field $k$. If the characteristic of $k$ is zero, then $G$ is smooth over $k$ by Lemma 8.2. If the characteristic of $k$ is $p > 0$, then we let $H = G_{\text{red}}$ be the reduction of $G$. By Divisors, Proposition 17.9 it suffices to show that $H$ has an ample invertible sheaf. (For an algebraic scheme over $k$ having an ample invertible sheaf is equivalent to being quasi-projective over $k$, see for example the very general More on Morphisms, Lemma 44.1.) By Lemma 7.6 we see that $H$ is a group scheme over $k$. By Lemma 8.4 we see that $H$ is smooth over $k$. This reduces us to the situation discussed in the next paragraph.

Let $G$ be a quasi-compact irreducible smooth group scheme over an algebraically closed field $k$. Observe that the local rings of $G$ are regular and hence UFDs (Varieties, Lemma 25.3 and More on Algebra, Lemma 104.7). The complement of a nonempty affine open of $G$ is the support of an effective Cartier divisor $D$. This follows from Divisors, Lemma 16.6. (Observe that $G$ is separated by Lemma 7.3.) We conclude there exists an effective Cartier divisor $D \subset G$ such that $G \setminus D$ is affine. We will use below that for any $n \geq 1$ and $g_1, \ldots, g_n \in G(k)$ the complement $G \setminus \bigcup Dg_i$ is affine. Namely, it is the intersection of the affine opens $G \setminus Dg_i \cong G \setminus D$ in the separated scheme $G$.

We may choose the top row of the diagram

$$
\begin{array}{ccc}
G & \leftarrow & U \\
\downarrow & & \downarrow \\
W & \leftarrow & V
\end{array}
$$

such that $U \neq \emptyset$, $j : U \to G$ is an open immersion, and $\pi$ is étale, see Morphisms, Lemma 34.20. There is a nonempty affine open $V \subset \mathbb{A}^d_k$ such that with $W = \pi^{-1}(V)$ the morphism $\pi' = \pi|_W : W \to V$ is finite étale. In particular $\pi'$ is finite locally free, say of degree $n$. Consider the effective Cartier divisor

$$D = \{(g, w) \mid m(g, j(w)) \in D\} \subset G \times W$$
(This is the restriction to $G \times W$ of the pullback of $D \subset G$ under the flat morphism $m : G \times G \to G$.) Consider the closed subset $T = (1 \times \pi')^{-1}(D) \subset G \times V$. Since $\pi'$ is finite locally free, every irreducible component of $T$ has codimension 1 in $G \times V$. Since $G \times V$ is smooth over $k$ we conclude these components are effective Cartier divisors (Divisors, Lemma 15.7 and lemmas cited above) and hence $T$ is the support of an effective Cartier divisor $E$ in $G \times V$. If $v \in V(k)$, then $(\pi')^{-1}(v) = \{w_1, \ldots, w_n\} \subset W(k)$ and we see that

$$E_v = \bigcup_{i=1, \ldots, n} D_j(w_i)^{-1}$$

in $G$ set theoretically. In particular we see that $G \setminus E_v$ is affine open (see above). Moreover, if $g \in G(k)$, then there exists a $v \in V$ such that $g \not\in E_v$. Namely, the set $W'$ of $w \in W$ such that $g \not\in D_j(w)^{-1}$ is nonempty open and it suffices to pick $v$ such that the fibre of $W' \to V$ over $v$ has $n$ elements.

Consider the invertible sheaf $\mathcal{M} = \mathcal{O}_{G \times V}(E)$ on $G \times V$. By Varieties, Lemma 30.5 the isomorphism class $\mathcal{L}$ of the restriction $\mathcal{M}_v = \mathcal{O}_v(E_v)$ is independent of $v \in V(k)$. On the other hand, for every $g \in G(k)$ we can find a $v$ such that $g \not\in E_v$ and such that $G \setminus E_v$ is affine. Thus the canonical section (Divisors, Definition 14.1) of $\mathcal{O}_v(E_v)$ corresponds to a section $s_v$ of $\mathcal{L}$ which does not vanish at $g$ and such that $G_{s_v}$ is affine. This means that $\mathcal{L}$ is ample by definition (Properties, Definition 26.1).

**Lemma 8.8.** Let $k$ be a field. Let $G$ be a locally algebraic group scheme over $k$. Then the center of $G$ is a closed subgroup scheme of $G$.

**Proof.** Let $\text{Aut}(G)$ denote the contravariant functor on the category of schemes over $k$ which associates to $S/k$ the set of automorphisms of the base change $G_S$ as a group scheme over $S$. There is a natural transformation

$$G \to \text{Aut}(G), \quad g \mapsto \text{in}_g$$

sending an $S$-valued point $g$ of $G$ to the inner automorphism of $G$ determined by $g$. The center $C$ of $G$ is by definition the kernel of this transformation, i.e., the functor which to $S$ associates those $g \in G(S)$ whose associated inner automorphism is trivial. The statement of the lemma is that this functor is representable by a closed subgroup scheme of $G$.

Choose an integer $n \geq 1$. Let $G_n \subset G$ be the $n$th infinitesimal neighbourhood of the identity element $e$ of $G$. For every scheme $S/k$ the base change $G_{n,S}$ is the $n$th infinitesimal neighbourhood of $e_S : S \to G_S$. Thus we see that there is a natural transformation $\text{Aut}(G) \to \text{Aut}(G_n)$ where the right hand side is the functor of automorphisms of $G_n$ as a scheme ($G_n$ isn’t in general a group scheme). Observe that $G_n$ is the spectrum of an artinian local ring $A_n$ with residue field $k$ which has finite dimension as a $k$-vector space (Varieties, Lemma 20.2). Since every automorphism of $G_n$ induces in particular an invertible linear map $A_n \to A_n$, we obtain transformations of functors

$$G \to \text{Aut}(G) \to \text{Aut}(G_n) \to \text{GL}(A_n)$$

1Using the material in Divisors, Section 17 we could take as effective Cartier divisor $E$ the norm of the effective Cartier divisor $D$ along the finite locally free morphism $1 \times \pi'$ bypassing some of the arguments.
The final group valued functor is representable, see Example 5.4, and the last arrow is visibly injective. Thus for every \( n \) we obtain a closed subgroup scheme
\[
H_n = \text{Ker}(G \to \text{Aut}(G_n)) = \text{Ker}(G \to \text{GL}(A_n)).
\]
As a first approximation we set \( H = \bigcap_{n \geq 1} H_n \) (scheme theoretic intersection). This is a closed subgroup scheme which contains the center \( \mathcal{C} \).

Let \( h \) be an \( S \)-valued point of \( H \) with \( S \) locally Noetherian. Then the automorphism \( \text{inn}_h \) induces the identity on all the closed subschemes \( G_n,S \). Consider the kernel \( K = \text{Ker}(\text{inn}_h : G_S \to G_S) \). This is a closed subgroup scheme of \( G_S \) over \( S \) containing the closed subschemes \( G_n,S \) for \( n \geq 1 \). This implies that \( K \) contains an open neighbourhood of \( e(S) \subset G_S \), see Algebra, Remark 50.6. Let \( G^0 \subset G \) be as in Proposition 7.11. Since \( G^0 \) is geometrically irreducible, we conclude that \( K \) contains \( G^0 \) for any nonempty open \( U \subset G^0 \) and any field extension \( k'/k \) we have \( U \cdot U^{-1} = G^0 \), see proof of Lemma 7.9. Applying this with \( S = H \) we find that \( G^0 \) and \( H \) are subgroup schemes of \( G \) whose points commute: for any scheme \( S \) and any \( S \)-valued points \( g \in G^0(S), h \in H(S) \) we have \( gh = hg \) in \( G(S) \).

Assume that \( k \) is algebraically closed. Then we can pick a \( k \)-valued point \( g_i \) in each irreducible component \( G_i \) of \( G \). Observe that in this case the connected components of \( G \) are the irreducible components of \( G \) are the translates of \( G^0 \) by our \( g_i \). We claim that
\[
C = H \cap \bigcap_i \text{Ker}(\text{inn}_{g_i} : G \to G) \quad \text{(scheme theoretic intersection)}
\]
Namely, \( C \) is contained in the right hand side. On the other hand, every \( S \)-valued point \( h \) of the right hand side commutes with \( G^0 \) and with \( g_i \) hence with everything in \( G = \bigcup G^0 g_i \).

The case of a general base field \( k \) follows from the result for the algebraic closure \( \overline{k} \) by descent. Namely, let \( A \subset G_{\overline{k}} \) the closed subgroup scheme representing the center of \( G_{\overline{k}} \). Then we have
\[
A \times_{\text{Spec}(k)} \text{Spec}(\overline{k}) = \text{Spec}(\overline{k}) \times_{\text{Spec}(k)} A
\]
as closed subschemes of \( G_{\overline{k} \otimes_k \overline{k}} \) by the functorial nature of the center. Hence we see that \( A \) descends to a closed subgroup scheme \( Z \subset G \) by Descent, Lemma 34.2 and Descent, Lemma 20.19. Then \( Z \) represents \( C \) (small argument omitted) and the proof is complete.  \( \square \)

### 9. Abelian varieties

An excellent reference for this material is Mumford’s book on abelian varieties, see [Mum70]. We encourage the reader to look there. There are many equivalent definitions; here is one.

**Definition 9.1.** Let \( k \) be a field. An abelian variety is a group scheme over \( k \) which is also a proper, geometrically integral variety over \( k \).

We prove a few lemmas about this notion and then we collect all the results together in Proposition 9.11.

**Lemma 9.2.** Let \( k \) be a field. Let \( A \) be an abelian variety over \( k \). Then \( A \) is projective.

**Proof.** This follows from Lemma 8.7 and More on Morphisms, Lemma 45.1  \( \square \)
An abelian variety is an abelian group scheme, i.e., the group law is invertible. Let \( A \)
where \( n \) is invertible. This works because the restriction of invertible modules on \( A \) means it is constant with value \( e \). By More on Morphisms, Lemma 9.3 there exists an open neighbourhood \( U \subset A \) of \( e \) such that \( h|_{U \times A} \) factors through some \( Z \subset U \times A \) finite over \( U \). This means that for \( x \in U(k) \) the morphism \( A \rightarrow A, y \mapsto xyx^{-1}y^{-1} \) takes finitely many values. Of course this means it is constant with value \( e \). Thus \( (x,y) \mapsto xyx^{-1}y^{-1} \) is constant with value \( e \) on \( U \times A \) which implies that the group law on \( A \) is abelian.

Let \( k \) be a field. Let \( A \) be an abelian variety over \( k \). Let \( \mathcal{L} \) be an invertible \( \mathcal{O}_A \)-module. Then there is an isomorphism \( m_{1,2,3}^* \mathcal{L} \otimes m_1^* \mathcal{L} \otimes m_2^* \mathcal{L} \otimes m_3^* \mathcal{L} \cong m_{1,2}^* \mathcal{L} \otimes m_{1,3}^* \mathcal{L} \otimes m_{2,3}^* \mathcal{L} \) of invertible modules on \( A \times_k A \times_k A \) where \( m_{i_1,...,i_t} : A \times_k A \times_k A \rightarrow A \) is the morphism \( (x_1,x_2,x_3) \mapsto \sum_i x_{i_j} \).

Let \( k \) be a field. Let \( A \) be an abelian variety over \( k \). Let \( \mathcal{L} \) be an invertible \( \mathcal{O}_A \)-module. Then
\[
\mathcal{M} = m_{1,2,3}^* \mathcal{L} \otimes m_1^* \mathcal{L} \otimes m_2^* \mathcal{L} \otimes m_3^* \mathcal{L} \otimes m_{1,2}^* \mathcal{L} \otimes m_{1,3}^* \mathcal{L} \otimes m_{2,3}^* \mathcal{L} \\
\cong m_{1,2}^* \mathcal{L} \otimes m_1^* \mathcal{L} \otimes m_2^* \mathcal{L} \otimes m_{1,2}^* \mathcal{L} \otimes m_{1,3}^* \mathcal{L} \otimes m_{2,3}^* \mathcal{L} \\
\cong \mathcal{O}_{A \times_k A}
\]
This works because the restriction of \( \mathcal{M} \) to \( A \times A \times e = A \times A \) is equal to
\[
[n] : A \rightarrow A\text{ sends } x \text{ to } x + x + \ldots + x \text{ with } n \text{ summands and where } [-1] : A \rightarrow A \text{ is the inverse of } A.
\]

Proof. Apply the theorem of the cube (More on Morphisms, Theorem 29.8) to the difference
\[
\mathcal{M} = m_{1,2,3}^* \mathcal{L} \otimes m_1^* \mathcal{L} \otimes m_2^* \mathcal{L} \otimes m_3^* \mathcal{L} \otimes m_{1,2}^* \mathcal{L} \otimes m_{1,3}^* \mathcal{L} \otimes m_{2,3}^* \mathcal{L} \\
\cong m_{1,2}^* \mathcal{L} \otimes m_1^* \mathcal{L} \otimes m_2^* \mathcal{L} \otimes m_{1,2}^* \mathcal{L} \otimes m_{1,3}^* \mathcal{L} \otimes m_{2,3}^* \mathcal{L} \\
\cong \mathcal{O}_{A \times_k A}
\]
where \( n_{i_1,...,i_t} : A \times_k A \rightarrow A \) is the morphism \( (x_1,x_2) \mapsto \sum_i x_{i_j} \). Similarly for \( A \times e \times A \) and \( e \times A \times A \).
Proof. Consider the morphism \( A \to A \times_k A \times_k A \), \( x \mapsto (x, x, -x) \) where \( -x = [-1](x) \). Pulling back the relation of Lemma 9.6 we obtain
\[
\mathcal{L} \otimes \mathcal{L} \otimes \mathcal{L} \otimes [-1]^{*} \mathcal{L} \cong [2]^{*} \mathcal{L}
\]
which proves the result for \( n = 2 \). By induction assume the result holds for \( 1, 2, \ldots, n \). Then consider the morphism \( A \to A \times_k A \times_k A \), \( x \mapsto (x, x, [n-1]x) \). Pulling back the relation of Lemma 9.6 we obtain
\[
[n + 1]^{*} \mathcal{L} \otimes \mathcal{L} \otimes \mathcal{L} \otimes [n - 1]^{*} \mathcal{L} \cong [2]^{*} \mathcal{L} \otimes [n]^{*} \mathcal{L} \otimes [n]^{*} \mathcal{L}
\]
and the result follows by elementary arithmetic. \( \square \)

Lemma 9.8. Let \( k \) be a field. Let \( A \) be an abelian variety over \( k \). Let \( [d] : A \to A \) be the multiplication by \( d \). Then \( [d] \) is finite locally free of degree \( d^{2 \dim(A)} \).

Proof. By Lemma 9.2 (and More on Morphisms, Lemma 45.1) we see that \( A \) has an ample invertible module \( \mathcal{L} \). Since \([-1] : A \to A \) is an automorphism, we see that \([-1]^{*} \mathcal{L} \) is an ample invertible \( \mathcal{O}_X \)-module as well. Thus \( \mathcal{N} = \mathcal{L} \otimes [-1]^{*} \mathcal{L} \) is ample, see Properties, Lemma 26.5. Since \( \mathcal{N} \cong [-1]^{*} \mathcal{N} \) we see that \( [d]^{*} \mathcal{N} \cong \mathcal{N} \otimes \mathcal{N}^{\otimes n^2} \) by Lemma 9.7.

To get a contradiction \( C \subset X \) be a proper curve contained in a fibre of \([d] \). Then \( \mathcal{N}^{\otimes d} \cong \mathcal{O}_C \) is an ample invertible \( \mathcal{O}_C \)-module of degree 0 which contradicts Varieties, Lemma 43.14 for example. (You can also use Varieties, Lemma 44.9.)

Thus every fibre of \([d] \) has dimension 0 and hence \([d] \) is finite for example by Cohomology of Schemes, Lemma 21.1. Moreover, since \( A \) is smooth over \( k \) by Lemma 9.4 we see that \([d] : A \to A \) is flat by Algebra, Lemma 127.1 (we also use that schemes smooth over fields are regular and that regular rings are Cohen-Macaulay, see Varieties, Lemma 25.3 and Algebra, Lemma 105.3). Thus \([d] \) is finite flat hence finite locally free by Morphisms, Lemma 46.2.

Finally, we come to the formula for the degree. By Varieties, Lemma 44.11 we see that
\[
\deg_{\mathcal{N}^{\otimes d^2}}(A) = \deg([d]) \deg_{\mathcal{N}}(A)
\]
Since the degree of \( A \) with respect to \( \mathcal{N}^{\otimes d^2} \), respectively \( \mathcal{N} \) is the coefficient of \( n^{\dim(A)} \) in the polynomial
\[
n \mapsto \chi(A, \mathcal{N}^{\otimes n^2}), \quad \text{respectively} \quad n \mapsto \chi(A, \mathcal{N}^{\otimes n})
\]
we see that \( \deg([d]) = d^{2 \dim(A)} \). \( \square \)

Lemma 9.9. Let \( k \) be a field. Let \( A \) be an abelian variety over \( k \). Then \([d] : A \to A \) is étale if and only if \( d \) is invertible in \( k \).

Proof. Observe that \([d](x + y) = [d](x) + [d](y) \). Since translation by a point is an automorphism of \( A \), we see that the set of points where \([d] : A \to A \) is étale is either empty or equal to \( A \) (some details omitted). Thus it suffices to check whether \([d] \) is étale at the unit \( e \in A(k) \). Since we know that \([d] \) is finite locally free (Lemma 9.8) to see that it is étale at \( e \) is equivalent to proving that \([d][d] : T_{A/k,e} \to T_{A/k,e} \) is injective. See Varieties, Lemma 16.8 and Morphisms, Lemma 34.16. By Lemma 6.4 we see that \([d][d] \) is given by multiplication by \( d \) on \( T_{A/k,e} \).

Lemma 9.10. Let \( k \) be a field of characteristic \( p > 0 \). Let \( A \) be an abelian variety over \( k \). The fibre of \([p] : A \to A \) over 0 has at most \( p^g \) distinct points.
Proof. To prove this, we may and do replace $k$ by the algebraic closure. By Lemma \ref{lem-grpd-sch}, the derivative of $[p]$ is multiplication by $p$ as a map $T_{A/k,e} \rightarrow T_{A/k,e}$ and hence is zero (compare with proof of Lemma \ref{lem-9-9}). Since $[p]$ commutes with translation we conclude that the derivative of $[p]$ is everywhere zero, i.e., that the induced map $[p]^* \Omega_{A/k} \rightarrow \Omega_{A/k}$ is zero. Looking at generic points, we find that the corresponding map $[p]^* : k(A) \rightarrow k(A)$ of function fields induces the zero map on $\Omega_{k(A)/k}$. Let $t_1, \ldots, t_g$ be a $p$-basis of $k(A)$ over $k$ (More on Algebra, Definition \ref{defn-45.1} and Lemma \ref{lem-45.2}). Then $[p]^*(t_i)$ has a $p$th root by Algebra, Lemma \ref{lem-152.2} We conclude that $k(A)[x_1, \ldots, x_g]/(x_1^p - t_1, \ldots, x_g^p - t_g)$ is a subextension of $[p]^* : k(A) \rightarrow k(A)$. Thus we can find an affine open $U \subset A$ such that $t_i \in \mathcal{O}_A(U)$ and $x_i \in \mathcal{O}_A([p]^{-1}(U))$.

We obtain a factorization

$$[p]^{-1}(U) \xrightarrow{\pi_1} \text{Spec}(\mathcal{O}(U)[x_1, \ldots, x_g]/(x_1^p - t_1, \ldots, x_g^p - t_g)) \xrightarrow{\pi_2} U$$

of $[p]$ over $U$. After shrinking $U$ we may assume that $\pi_1$ is finite locally free (for example by generic flatness – actually it is already finite locally free in our case). By Lemma \ref{lem-9.8} we see that $[p]$ has degree $p^g$. Since $\pi_2$ has degree $p^g$ we see that $\pi_1$ has degree $p^g$ as well. The morphism $\pi_2$ is a universal homeomorphism hence the fibres are singletons. We conclude that the (set theoretic) fibres of $[p]^{-1}(U) \rightarrow U$ are the fibres of $\pi_1$. Hence they have at most $p^g$ elements. Since $[p]$ is a homomorphism of group schemes over $k$, the fibre of $[p] : A(k) \rightarrow A(k)$ has the same cardinality for every $a \in A(k)$ and the proof is complete. \hfill $\square$

\begin{proposition}
\textbf{Proposition \ref{prop-9.11}.} Let $A$ be an abelian variety over a field $k$. Then

(1) $A$ is projective over $k$,
(2) $A$ is a commutative group scheme,
(3) the morphism $[n] : A \rightarrow A$ is surjective for all $n \geq 1$,
(4) if $k$ is algebraically closed, then $A(k)$ is a divisible abelian group,
(5) $A[n] = \ker([n] : A \rightarrow A)$ is a finite group scheme of degree $n^{2 \dim A}$ over $k$,
(6) $A[n]$ is étale over $k$ if and only if $n \in k^*$,
(7) if $n \in k^*$ and $k$ is algebraically closed, then $A(k)[n] \cong (\mathbb{Z}/n\mathbb{Z})^{\oplus 2 \dim(A)},$
(8) if $k$ is algebraically closed of characteristic $p > 0$, then there exists an integer $0 \leq f \leq \dim(A)$ such that $A(k)[p^m] \cong (\mathbb{Z}/p^m\mathbb{Z})^{\oplus f}$ for all $m \geq 1$.

\end{proposition}

\textbf{Proof.} Part (1) follows from Lemma \ref{lem-9.2}. Part (2) follows from Lemma \ref{lem-9.5}. Part (3) follows from Lemma \ref{lem-9.8}. If $k$ is algebraically closed then surjective morphisms of varieties over $k$ induce surjective maps on $k$-rational points, hence (4) follows from (3). Part (5) follows from Lemma \ref{lem-9.8} and the fact that a base change of a finite locally free morphism of degree $N$ is a finite locally free morphism of degree $N$. Part (6) follows from Lemma \ref{lem-9.9}. Namely, if $n$ is invertible in $k$, then $[n]$ is étale and hence $A[n]$ is étale over $k$. On the other hand, if $n$ is not invertible in $k$, then $[n]$ is not étale at $e$ and it follows that $A[n]$ is not étale over $k$ at $e$ (use Morphisms, Lemmas \ref{lem-34.16} and \ref{lem-33.15}).

Assume $k$ is algebraically closed. Set $g = \dim(A)$. Proof of (7). Let $\ell$ be a prime number which is invertible in $k$. Then we see that

$$A[\ell](k) = A(k)[\ell]$$

is a finite abelian group, annihilated by $\ell$, of order $\ell^{2g}$. It follows that it is isomorphic to $(\mathbb{Z}/\ell\mathbb{Z})^{2g}$ by the structure theory for finite abelian groups. Next, we consider
the short exact sequence

\[ 0 \rightarrow A(k)[\ell] \rightarrow A(k)[\ell^2] \rightarrow A(k)[\ell] \rightarrow 0 \]

Arguing similarly as above we conclude that \( A(k)[\ell^2] \cong (\mathbb{Z}/\ell^2\mathbb{Z})^{2g} \). By induction on the exponent we find that \( A(k)[\ell^m] \cong (\mathbb{Z}/\ell^m\mathbb{Z})^{2g} \). For composite integers \( n \) prime to the characteristic of \( k \) we take primary parts and we find the correct shape of the \( n \)-torsion in \( A(k) \). The proof of (8) proceeds in exactly the same way, using that Lemma 9.10 gives \( A(k)[p] \cong (\mathbb{Z}/p\mathbb{Z})^{\ell_f} \) for some \( 0 \leq f \leq g \).

10. Actions of group schemes

022Y Let \((G, m)\) be a group and let \( V \) be a set. Recall that a (left) action of \( G \) on \( V \) is given by a map \( a : G \times V \rightarrow V \) such that

1. (associativity) \( a(m(g, g'), v) = a(g, a(g', v)) \) for all \( g, g' \in G \) and \( v \in V \), and
2. (identity) \( a(e, v) = v \) for all \( v \in V \).

We also say that \( V \) is a \( G \)-set (this usually means we drop the \( a \) from the notation – which is abuse of notation). A map of \( G \)-sets \( \psi : V \rightarrow V' \) is any set map such that \( \psi(a(g, v)) = a(g, \psi(v)) \) for all \( v \in V \).

022Z **Definition 10.1.** Let \( S \) be a scheme. Let \((G, m)\) be a group scheme over \( S \).

1. An action of \( G \) on the scheme \( X/S \) is a morphism \( a : G \times_S X \rightarrow X \) over \( S \) such that for every \( T/S \) the map \( a : G(T) \times X(T) \rightarrow X(T) \) defines the structure of a \( G(T) \)-set on \( X(T) \).
2. Suppose that \( X, Y \) are schemes over \( S \) each endowed with an action of \( G \). An equivariant or more precisely a \( G \)-equivariant morphism \( \psi : X \rightarrow Y \) is a morphism of schemes over \( S \) such that for every \( T/S \) the map \( \psi : X(T) \rightarrow Y(T) \) is a morphism of \( G(T) \)-sets.

In situation (1) this means that the diagrams

\[ \begin{array}{ccc}
G \times_S G \times_S X & \xrightarrow{1_G \times a} & G \times_S X \\
\downarrow{m \times 1_X} & & \downarrow{a} \\
G \times_S X & \xrightarrow{a} & X \\
\end{array} \]

\[ \begin{array}{ccc}
G \times_S X & \xrightarrow{e \times 1_X} & X \\
\downarrow{1_X} & & \downarrow{1_X} \\
X & & X
\end{array} \]

are commutative. In situation (2) this just means that the diagram

\[ \begin{array}{ccc}
G \times_S X & \xrightarrow{\text{id} \times f} & G \times_S Y \\
\downarrow{a} & & \downarrow{a} \\
X & \xrightarrow{f} & Y
\end{array} \]

commutes.

07S1 **Definition 10.2.** Let \( S, G \rightarrow S \), and \( X \rightarrow S \) as in Definition 10.1. Let \( a : G \times_S X \rightarrow X \) be an action of \( G \) on \( X/S \). We say the action is free if for every scheme \( T \) over \( S \) the action \( a : G(T) \times X(T) \rightarrow X(T) \) is a free action of the group \( G(T) \) on the set \( X(T) \).

07S2 **Lemma 10.3.** Situation as in Definition 10.2. The action \( a \) is free if and only if \( G \times_S X \rightarrow X \times_S X, \quad (g, x) \mapsto (a(g, x), x) \)

is a monomorphism.

**Proof.** Immediate from the definitions.

\[ \square \]
11. Principal homogeneous spaces

In Cohomology on Sites, Definition 5.1 we have defined a torsor for a sheaf of groups on a site. Suppose \( \tau \in \{ \text{Zariski, étale, smooth, syntomic, fppf} \} \) is a topology and \((G, m)\) is a group scheme over \( S \). Since \( \tau \) is stronger than the canonical topology (see Descent, Lemma 10.7) we see that \( G \) (see Sites, Definition 12.3) is a sheaf of groups on \((\text{Sch}/S)_\tau\). Hence we already know what it means to have a torsor for \( G \) on \((\text{Sch}/S)_\tau\). A special situation arises if this sheaf is representable. In the following definitions we define directly what it means for the representing scheme to be a \( G \)-torsor.

**Definition 11.1.** Let \( S \) be a scheme. Let \((G, m)\) be a group scheme over \( S \). Let \( X \) be a scheme over \( S \), and let \( a : G \times_S X \to X \) be an action of \( G \) on \( X \).

1. We say \( X \) is a pseudo \( G \)-torsor or that \( X \) is formally principally homogeneous under \( G \) if the induced morphism of schemes \( G \times_S X \to X \times_S X \), \((g, x) \mapsto (a(g, x), x)\) is an isomorphism of schemes over \( S \).
2. A pseudo \( G \)-torsor \( X \) is called trivial if there exists an \( G \)-equivariant isomorphism \( G \to X \) over \( S \) where \( G \) acts on \( G \) by left multiplication.

It is clear that if \( S' \to S \) is a morphism of schemes then the pullback \( X_{S'} \) of a pseudo \( G \)-torsor over \( S \) is a pseudo \( G_{S'} \)-torsor over \( S' \).

**Lemma 11.2.** In the situation of Definition 11.1.

1. The scheme \( X \) is a pseudo \( G \)-torsor if and only if for every scheme \( T \) over \( S \) the set \( X(T) \) is either empty or the action of the group \( G(T) \) on \( X(T) \) is simply transitive.
2. A pseudo \( G \)-torsor \( X \) is trivial if and only if the morphism \( X \to S \) has a section.

**Proof.** Omitted. \( \square \)

**Definition 11.3.** Let \( S \) be a scheme. Let \((G, m)\) be a group scheme over \( S \). Let \( X \) be a pseudo \( G \)-torsor over \( S \).

1. We say \( X \) is a principal homogeneous space or a \( G \)-torsor if there exists a fpqc covering \( \{ S_i \to S \}_{i \in I} \) such that each \( X_{S_i} \to S_i \) has a section (i.e., is a trivial pseudo \( G_{S_i} \)-torsor).
2. Let \( \tau \in \{ \text{Zariski, étale, smooth, syntomic, fppf} \} \). We say \( X \) is a \( G \)-torsor in the \( \tau \) topology, or a \( \tau \) \( G \)-torsor, or simply a \( \tau \) torsor if there exists a \( \tau \) covering \( \{ S_i \to S \}_{i \in I} \) such that each \( X_{S_i} \to S_i \) has a section.
3. If \( X \) is a \( G \)-torsor, then we say that it is quasi-isotrivial if it is a torsor for the étale topology.
4. If \( X \) is a \( G \)-torsor, then we say that it is locally trivial if it is a torsor for the Zariski topology.

We sometimes say “let \( X \) be a \( G \)-torsor over \( S \)” to indicate that \( X \) is a scheme over \( S \) equipped with an action of \( G \) which turns it into a principal homogeneous space over \( S \). Next we show that this agrees with the notation introduced earlier when both apply.

---

\( ^2 \)This means that the default type of torsor is a pseudo torsor which is trivial on an fpqc covering. This is the definition in [ABD+ 66, Exposé IV, 6.5]. It is a little bit inconvenient for us as we most often work in the fppf topology.
Lemma 11.4. Let $S$ be a scheme. Let $(G, m)$ be a group scheme over $S$. Let $X$ be a scheme over $S$, and let $a : G \times_S X \to X$ be an action of $G$ on $X$. Let $\tau \in \{\text{Zariski, étale, smooth, syntomic, fppf}\}$. Then $X$ is a $G$-torsor in the $\tau$-topology if and only if $X$ is a $G$-torsor on $(\text{Sch}/S)_\tau$.

Proof. Omitted. □

Remark 11.5. Let $(G, m)$ be a group scheme over the scheme $S$. In this situation we have the following natural types of questions:

1. If $X \to S$ is a pseudo $G$-torsor and $X \to S$ is surjective, then is $X$ necessarily a $G$-torsor?
2. Is every $G$-torsor on $(\text{Sch}/S)_{\text{fppf}}$ representable? In other words, does every $G$-torsor come from a fppf $G$-torsor?
3. Is every $G$-torsor an fppf (resp. smooth, resp. étale, resp. Zariski) torsor?

In general the answers to these questions is no. To get a positive answer we need to impose additional conditions on $G \to S$. For example: If $S$ is the spectrum of a field, then the answer to (1) is yes because then $\{X \to S\}$ is a fpqc covering trivializing $X$. If $G \to S$ is affine, then the answer to (2) is yes (insert future reference here). If $G = \text{GL}_{n,S}$ then the answer to (3) is yes and in fact any $\text{GL}_{n,S}$-torsor is locally trivial (insert future reference here).

12. Equivariant quasi-coherent sheaves

We think of “functions” as dual to “space”. Thus for a morphism of spaces the map on functions goes the other way. Moreover, we think of the sections of a sheaf of modules as “functions”. This leads us naturally to the direction of the arrows chosen in the following definition.

Definition 12.1. Let $S$ be a scheme, let $(G, m)$ be a group scheme over $S$, and let $a : G \times_S X \to X$ be an action of the group scheme $G$ on $X/S$. An $G$-equivariant quasi-coherent $O_X$-module, or simply a equivariant quasi-coherent $O_X$-module, is a pair $(F, \alpha)$, where $F$ is a quasi-coherent $O_X$-module, and $\alpha$ is a $O_{G \times_S X}$-module map

\[
\alpha : a^* F \to \text{pr}_1^* F
\]

where $\text{pr}_1 : G \times_S X \to X$ is the projection such that

1. the diagram

\[
\begin{align*}
(1_G \times a)^* \text{pr}_1^* F &\xrightarrow{(m \times 1_X)^* \alpha} (m \times 1_X)^* a^* F \\
(1_G \times a)^* a^* F &\xrightarrow{\text{pr}_1^* \alpha} \text{pr}_2^* F
\end{align*}
\]

is a commutative in the category of $O_{G \times_S G \times S X}$-modules, and
2. the pullback

\[
(e \times 1_X)^* \alpha : F \to F
\]

is the identity map.

For explanation compare with the relevant diagrams of Equation (10.1.1).

Note that the commutativity of the first diagram guarantees that $(e \times 1_X)^* \alpha$ is an idempotent operator on $F$, and hence condition (2) is just the condition that it is an isomorphism.
Lemma 12.2. Let $S$ be a scheme. Let $G$ be a group scheme over $S$. Let $f : Y \to X$ be a $G$-equivariant morphism between $S$-schemes endowed with $G$-actions. Then pullback $f^*$ given by $(\mathcal{F}, \alpha) \mapsto (f^*\mathcal{F}, (1_G \times f)^*\alpha)$ defines a functor from the category of $G$-equivariant sheaves on $X$ to the category of quasi-coherent $G$-equivariant sheaves on $Y$.

Proof. Omitted. □

Let us give an example.

Example 12.3. Let $A$ be a $\mathbb{Z}$-graded ring, i.e., $A$ comes with a direct sum decomposition $A = \bigoplus_{n \in \mathbb{Z}} A_n$ and $A_n \cdot A_m \subset A_{n+m}$. Set $X = \text{Spec}(A)$. Then we obtain a $G$-action

$$a : G_m \times X \to X$$

by the ring map $\mu : A \to A \otimes \mathbb{Z}[x, x^{-1}], f \mapsto f \otimes x^{\deg(f)}$. Namely, to check this we have to verify that

$$A \xrightarrow{\mu} A \otimes \mathbb{Z}[x, x^{-1}] \xrightarrow{1 \otimes m} A \otimes \mathbb{Z}[x, x^{-1}] \otimes \mathbb{Z}[x, x^{-1}]$$

where $m(x) = x \otimes x$, see Example 5.1. This is immediately clear when evaluating on a homogeneous element. Suppose that $M$ is a graded $A$-module. Then we obtain a $G_m$-equivariant quasi-coherent $\mathcal{O}_X$-module $\mathcal{F} = \tilde{M}$ by using $\alpha$ as in Definition 12.1 corresponding to the $A \otimes \mathbb{Z}[x, x^{-1}]$-module map

$$M \otimes_{A, \mu} (A \otimes \mathbb{Z}[x, x^{-1}]) \to M \otimes_{A, \text{id}_A \otimes 1} (A \otimes \mathbb{Z}[x, x^{-1}])$$

sending $m \otimes 1 \otimes 1$ to $m \otimes 1 \otimes x^{\deg(m)}$ for $m \in M$ homogeneous.

Lemma 12.4. Let $a : G_m \times X \to X$ be an action on an affine scheme. Then $X$ is the spectrum of a $\mathbb{Z}$-graded ring and the action is as in Example 12.3.

Proof. Let $f \in A = \Gamma(X, \mathcal{O}_X)$. Then we can write

$$a^2(f) = \sum_{n \in \mathbb{Z}} f_n \otimes x^n \quad \text{in} \quad A \otimes \mathbb{Z}[x, x^{-1}] = \Gamma(G_m \times X, \mathcal{O}_{G_m \times X})$$

as a finite sum with $f_n$ in $A$ uniquely determined. Thus we obtain maps $A \to A$, $f \mapsto f_n$. Since $a$ is an action, if we evaluate at $x = 1$, we see $f = \sum f_n$. Since $a$ is an action we find that

$$\sum (f_n)_m \otimes x^n \otimes x^n = \sum f_n x^n \otimes x^n$$

(compare with computation in Example 12.3). Thus $(f_n)_m = 0$ if $n \neq m$ and $(f_n)_n = f_n$. Thus if we set

$$A_n = \{ f \in A \mid f_n = f \}$$

then we get $A = \sum A_n$. On the other hand, the sum has to be direct since $f = 0$ implies $f_n = 0$ in the situation above. □

Lemma 12.5. Let $A$ be a graded ring. Let $X = \text{Spec}(A)$ with action $a : G_m \times X \to X$ as in Example 12.3. Let $\mathcal{F}$ be a $G_m$-equivariant quasi-coherent $\mathcal{O}_X$-module. Then $M = \Gamma(X, \mathcal{F})$ has a canonical grading such that it is a graded $A$-module and such that the isomorphism $\tilde{M} \to \mathcal{F}$ (Schemes, Lemma 7.4) is an isomorphism of
**G**\textsuperscript{m} -equivariant modules where the **G**\textsuperscript{m} -equivariant structure on \( \widetilde{M} \) is the one from Example 12.3.

**Proof.** You can either prove this by repeating the arguments of Lemma 12.4 for the module \( M \). Alternatively, you can consider the scheme \((X', O_{X'}) = (X, O_X \oplus F)\) where \( F \) is viewed as an ideal of square zero. There is a natural action \( a' : \text{**G**}_m \times X' \to X' \) defined using the action on \( X \) and on \( F \). Then apply Lemma 12.4 to \( X' \) and conclude. (The nice thing about this argument is that it immediately shows that the grading on \( A \) and \( M \) are compatible, i.e., that \( M \) is a graded \( A \)-module.) Details omitted.

\section{Groupoids}

Recall that a groupoid is a category in which every morphism is an isomorphism, see Categories, Definition 2.5. Hence a groupoid has a set of objects \( \text{Ob} \), a set of arrows \( \text{Arrows} \), a *source* and *target* map \( s, t : \text{Arrows} \to \text{Ob} \), and a *composition* law \( c : \text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \to \text{Arrows} \). These maps satisfy exactly the following axioms:

\begin{enumerate}
  \item (associativity) \( c \circ (1, c) = c \circ (c, 1) \) as maps \( \text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \times_{s, \text{Ob}, t} \text{Arrows} \to \text{Arrows} \),
  \item (identity) there exists a map \( e : \text{Ob} \to \text{Arrows} \) such that
    \begin{enumerate}
      \item \( s \circ e = t \circ e = \text{id} \) as maps \( \text{Ob} \to \text{Ob} \),
      \item \( c \circ (1, e \circ s) = c \circ (e \circ t, 1) = 1 \) as maps \( \text{Arrows} \to \text{Arrows} \),
    \end{enumerate}
  \item (inverse) there exists a map \( i : \text{Arrows} \to \text{Arrows} \) such that
    \begin{enumerate}
      \item \( s \circ i = t, t \circ i = s \) as maps \( \text{Arrows} \to \text{Ob} \), and
      \item \( c \circ (1, i) = e \circ t \) and \( c \circ (i, 1) = e \circ s \) as maps \( \text{Arrows} \to \text{Arrows} \).
    \end{enumerate}
\end{enumerate}

If this is the case the maps \( e \) and \( i \) are uniquely determined and \( i \) is a bijection. Note that if \((\text{Ob}', \text{Arrows}', s', t', c')\) is a second groupoid category, then a functor \( f : (\text{Ob}, \text{Arrows}, s, t, c) \to (\text{Ob}', \text{Arrows}', s', t', c')\) is given by a pair of set maps \( f : \text{Ob} \to \text{Ob}' \) and \( f : \text{Arrows} \to \text{Arrows}' \) such that \( s' \circ f = f \circ s, t' \circ f = f \circ t, \) and \( c' \circ (f, f) = f \circ c \). The compatibility with identity and inverse is automatic. We will use this below. (Warning: The compatibility with identity has to be imposed in the case of general categories.)

**Definition** 13.1. Let \( S \) be a scheme.

\begin{enumerate}
  \item A *groupoid scheme over \( S \)*, or simply a *groupoid over \( S \)* is a quintuple \((U, R, s, t, c)\) where \( U \) and \( R \) are schemes over \( S \), and \( s, t : R \to U \) and \( c : R \times_{s, U, t} R \to R \) are morphisms of schemes over \( S \) with the following property: For any scheme \( T \) over \( S \) the quintuple
    \[(U(T), R(T), s, t, c)\]
  is a groupoid category in the sense described above.
  \item A *morphism \( f : (U, R, s, t, c) \to (U', R', s', t', c') \) of groupoid schemes over \( S \) is given by morphisms of schemes \( f : U \to U' \) and \( f : R \to R' \) with the following property: For any scheme \( T \) over \( S \) the maps \( f \) define a functor from the groupoid category \((U(T), R(T), s, t, c)\) to the groupoid category \((U'(T), R'(T), s', t', c')\).
\end{enumerate}

Let \((U, R, s, t, c)\) be a groupoid over \( S \). Note that, by the remarks preceding the definition and the Yoneda lemma, there are unique morphisms of schemes \( e : U \to R \) and \( i : R \to R \) over \( S \) such that for every scheme \( T \) over \( S \) the induced map
\( e : U(T) \to R(T) \) is the identity, and \( i : R(T) \to R(T) \) is the inverse of the groupoid category. The septuple \((U, R, s, t, c, e, i)\) satisfies commutative diagrams corresponding to each of the axioms (1), (2)(a), (2)(b), (3)(a) and (3)(b) above, and conversely given a septuple with this property the quintuple \((U, R, s, t, c)\) is a groupoid scheme. Note that \( i \) is an isomorphism, and \( e \) is a section of both \( s \) and \( t \). Moreover, given a groupoid scheme over \( S \) we denote

\[
j = (t, s) : R \to U \times_S U
\]

which is compatible with our conventions in Section 3 above. We sometimes say “let \((U, R, s, t, c, e, i)\) be a groupoid over \( S\)” to stress the existence of identity and inverse.

**Lemma 13.2.** Given a groupoid scheme \((U, R, s, t, c)\) over \( S \) the morphism \( j : R \to U \times_S U \) is a pre-equivalence relation.

**Proof.** Omitted. This is a nice exercise in the definitions. \( \square \)

**Lemma 13.3.** Given an equivalence relation \( j : R \to U \) over \( S \) there is a unique way to extend it to a groupoid \((U, R, s, t, c)\) over \( S \).

**Proof.** Omitted. This is a nice exercise in the definitions. \( \square \)

**Lemma 13.4.** Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid over \( S \). In the commutative diagram

\[
\begin{array}{ccc}
U & \xrightarrow{t} & U \\
\downarrow & & \downarrow \\
R & \xrightarrow{pr_0} & R \\
\downarrow & & \downarrow \\
U & \xleftarrow{s} & R
\end{array}
\]

the two lower squares are fibre product squares. Moreover, the triangle on top (which is really a square) is also cartesian.

**Proof.** Omitted. Exercise in the definitions and the functorial point of view in algebraic geometry. \( \square \)

**Lemma 13.5.** Let \( S \) be a scheme. Let \((U, R, s, t, c, e, i)\) be a groupoid over \( S \). The diagram

\[
\begin{array}{ccc}
R \times_{U \times U} R & \xrightarrow{pr_1} & R & \xrightarrow{s} & U \\
\downarrow & & \downarrow & & \downarrow \\
R \times_{s, U, t} R & \xrightarrow{pr_0} & R & \xrightarrow{id} & R \\
\downarrow & & \downarrow & & \downarrow \\
R & \xrightarrow{\bar{c}} & R & \xrightarrow{s} & U \\
\downarrow & & \downarrow & & \downarrow \\
U & \xleftarrow{t} & U
\end{array}
\]

is commutative. The two top rows are isomorphic via the vertical maps given. The two lower left squares are cartesian.
**Proof.** The commutativity of the diagram follows from the axioms of a groupoid. Note that, in terms of groupoids, the top left vertical arrow assigns to a pair of morphisms \((\alpha, \beta)\) with the same target, the pair of morphisms \((\alpha, \alpha^{-1} \circ \beta)\). In any groupoid this defines a bijection between Arrows \(\times_{\text{Ob}, t} \text{Arrows}\) and Arrows \(\times_{s, \text{Ob}, t} \text{Arrows}\). Hence the second assertion of the lemma. The last assertion follows from Lemma 13.4. \(\square\)

**Lemma 13.6.** Let \((U, R, s, t, c)\) be a groupoid over a scheme \(S\). Let \(S' \to S\) be a morphism. Then the base changes \(U' = S' \times_S U, R' = S' \times_S R\) endowed with the base changes \(s', t', c'\) of the morphisms \(s, t, c\) form a groupoid scheme \((U', R', s', t', c')\) over \(S'\) and the projections determine a morphism \((U', R', s', t', c') \to (U, R, s, t, c)\) of groupoid schemes over \(S\).

**Proof.** Omitted. Hint: \(R' \times_{s'} U' \times_{t'} R' = S' \times_S (R \times_{s, U, t} R)\). \(\square\)

### 14. Quasi-coherent sheaves on groupoids

**Definition 14.1.** Let \(S\) be a scheme, let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). A quasi-coherent module on \((U, R, s, t, c)\) is a pair \((\mathcal{F}, \alpha)\), where \(\mathcal{F}\) is a quasi-coherent \(\mathcal{O}_U\)-module, and \(\alpha\) is a \(\mathcal{O}_R\)-module map

\[
\alpha : t^*\mathcal{F} \to s^*\mathcal{F}
\]

such that

1. the diagram

\[
\begin{array}{ccc}
\text{pr}_1^*t^*\mathcal{F} & \xrightarrow{\text{pr}_1^*} & \text{pr}_1^*s^*\mathcal{F} \\
\downarrow \text{pr}_0^*s^*\mathcal{F} & & \downarrow \text{pr}_0^*t^*\mathcal{F} \\
\text{c}^*s^*\mathcal{F} & & \text{c}^*t^*\mathcal{F}
\end{array}
\]

is a commutative in the category of \(\mathcal{O}_{R \times_{s, U, t} R}\)-modules, and

2. the pullback

\[
e^*\alpha : \mathcal{F} \to \mathcal{F}
\]

is the identity map.

Compare with the commutative diagrams of Lemma 13.4.

The commutativity of the first diagram forces the operator \(e^*\alpha\) to be idempotent. Hence the second condition can be reformulated as saying that \(e^*\alpha\) is an isomorphism. In fact, the condition implies that \(\alpha\) is an isomorphism.

**Lemma 14.2.** Let \(S\) be a scheme, let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). If \((\mathcal{F}, \alpha)\) is a quasi-coherent module on \((U, R, s, t, c)\) then \(\alpha\) is an isomorphism.

**Proof.** Pull back the commutative diagram of Definition 14.1 by the morphism \((i, 1) : R \to R \times_{s, U, t} R\). Then we see that \(i^*\alpha \circ \alpha = s^*e^*\alpha\). Pulling back by the morphism \((1, i)\) we obtain the relation \(\alpha \circ i^*\alpha = t^*e^*\alpha\). By the second assumption these morphisms are the identity. Hence \(i^*\alpha\) is an inverse of \(\alpha\). \(\square\)
Lemma 14.3. Let $S$ be a scheme. Consider a morphism $f : (U, R, s, t, c) \to (U', R', s', t', c')$ of groupoid schemes over $S$. Then pullback $f^*$ given by

$$(F, \alpha) \mapsto (f^*F, f^*\alpha)$$

defines a functor from the category of quasi-coherent sheaves on $(U', R', s', t', c')$ to
the category of quasi-coherent sheaves on $(U, R, s, t, c)$.

Proof. Omitted. \[\square\]

Lemma 14.4. Let $S$ be a scheme. Consider a morphism $f : (U, R, s, t, c) \to (U', R', s', t', c')$ of groupoid schemes over $S$. Assume that

1. $f : U \to U'$ is quasi-compact and quasi-separated,
2. the square

$$
\begin{array}{ccc}
R & \xrightarrow{f} & R' \\
\downarrow t & & \downarrow t' \\
U & \xrightarrow{f} & U'
\end{array}
$$

is cartesian, and
3. $s'$ and $t'$ are flat.

Then pushforward $f_*$ given by

$$(F, \alpha) \mapsto (f_*F, f_*\alpha)$$

defines a functor from the category of quasi-coherent sheaves on $(U, R, s, t, c)$ to
the category of quasi-coherent sheaves on $(U', R', s', t', c')$ which is right adjoint to
pullback as defined in Lemma 14.3.

Proof. Since $U \to U'$ is quasi-compact and quasi-separated we see that $f_*$ transforms
quasi-coherent sheaves into quasi-coherent sheaves (Schemes, Lemma 24.1). Moreover, since the squares

$$
\begin{array}{ccc}
R & \xrightarrow{f} & R' \\
\downarrow t & & \downarrow t' \\
U & \xrightarrow{f} & U'
\end{array}
$$

and

$$
\begin{array}{ccc}
R & \xrightarrow{f} & R' \\
\downarrow s & & \downarrow s' \\
U & \xrightarrow{f} & U'
\end{array}
$$

are cartesian we find that $(t')^*f_*F = f_*t^*F$ and $(s')^*f_*F = f_*s^*F$, see Cohomology of Schemes, Lemma 5.2. Thus it makes sense to think of $f_*\alpha$ as a map
$(t')^*f_*F \to (s')^*f_*F$. A similar argument shows that $f_*\alpha$ satisfies the cocycle condition. The functor is adjoint to the pullback functor since pullback and push-
forward on modules on ringed spaces are adjoint. Some details omitted. \[\square\]

Lemma 14.5. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. The category of quasi-coherent modules on $(U, R, s, t, c)$ has colimits.

Proof. Let $i \mapsto (F_i, \alpha_i)$ be a diagram over the index category $\mathcal{I}$. We can form the colimit $\mathcal{F} = \text{colim} F_i$ which is a quasi-coherent sheaf on $U$, see Schemes, Section 24. Since colimits commute with pullback we see that $s^*\mathcal{F} = \text{colim} s^* F_i$ and similarly $t^*\mathcal{F} = \text{colim} t^* F_i$. Hence we can set $\alpha = \text{colim} \alpha_i$. We omit the proof that $(\mathcal{F}, \alpha)$ is the colimit of the diagram in the category of quasi-coherent modules on $(U, R, s, t, c)$. \[\square\]
Lemma 14.6. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. If $s$, $t$ are flat, then the category of quasi-coherent modules on $(U, R, s, t, c)$ is abelian.

Proof. Let $\varphi : (\mathcal{F}, \alpha) \to (\mathcal{G}, \beta)$ be a homomorphism of quasi-coherent modules on $(U, R, s, t, c)$. Since $s$ is flat we see that

$$0 \to s^* \text{Ker}(\varphi) \to s^* \mathcal{F} \to s^* \mathcal{G} \to s^* \text{Coker}(\varphi) \to 0$$

is exact and similarly for pullback by $t$. Hence $\alpha$ and $\beta$ induce isomorphisms $\kappa : t^* \text{Ker}(\varphi) \to s^* \text{Ker}(\varphi)$ and $\lambda : t^* \text{Coker}(\varphi) \to s^* \text{Coker}(\varphi)$ which satisfy the cocycle condition. Then it is straightforward to verify that $(\text{Ker}(\varphi), \kappa)$ and $(\text{Coker}(\varphi), \lambda)$ are a kernel and cokernel in the category of quasi-coherent modules on $(U, R, s, t, c)$. Moreover, the condition $\text{Coin}(\varphi) = \text{Im}(\varphi)$ follows because it holds over $U$. \hfill $\square$

15. Colimits of quasi-coherent modules

In this section we prove some technical results saying that under suitable assumptions every quasi-coherent module on a groupoid is a filtered colimit of “small” quasi-coherent modules.

Lemma 15.1. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume $s, t$ are flat, quasi-compact, and quasi-separated. For any quasi-coherent module $\mathcal{G}$ on $U$, there exists a canonical isomorphism $\alpha : t^* s^* \mathcal{G} \to s^* t^* s^* \mathcal{G}$ which turns $(t^* s^* \mathcal{G}, \alpha)$ into a quasi-coherent module on $(U, R, s, t, c)$. This construction defines a functor

$$\text{Qcoh}(O_U) \to \text{Qcoh}(U, R, s, t, c)$$

which is a right adjoint to the forgetful functor $(\mathcal{F}, \beta) \mapsto \mathcal{F}$.

Proof. The pushforward of a quasi-coherent module along a quasi-compact and quasi-separated morphism is quasi-coherent, see Schemes, Lemma 24.1. Hence $t^* s^* \mathcal{G}$ is quasi-coherent. With notation as in Lemma 13.4 we have

$$t^* t^* s^* \mathcal{G} = \text{pr}_{0,s} c^* s^* \mathcal{G} = \text{pr}_{0,s} \text{pr}_1^* s^* \mathcal{G} = s^* t^* s^* \mathcal{G}$$

The middle equality because $s \circ c = s \circ \text{pr}_1$ as morphisms $R \times_{s, U, t} R \to U$, and the first and the last equality because we know that base change and pushforward commute in these steps by Cohomology of Schemes, Lemma 5.2.

To verify the cocycle condition of Definition 14.1 for $\alpha$ and the adjointness property we describe the construction $\mathcal{G} \mapsto (\mathcal{G}, \alpha)$ in another way. Consider the groupoid scheme $(R, R \times_{s, U, s} R, \text{pr}_{0,1}, \text{pr}_0, \text{pr}_{02})$ associated to the equivalence relation $R \times_{s, U, s} R$ on $R$, see Lemma 13.3. There is a morphism

$$f : (R, R \times_{s, U, s} R, \text{pr}_{1,0}, \text{pr}_0, \text{pr}_{02}) \to (U, R, s, t, c)$$

of groupoid schemes given by $t : R \to U$ and $R \times_{t, U, t} R \to R$ given by $(r_0, r_1) \mapsto r_0 \circ r_1^{-1}$ (we omit the verification of the commutativity of the required diagrams). Since $t, s : R \to U$ are quasi-compact, quasi-separated, and flat, and since we have a cartesian square

$$\begin{array}{ccc}
R \times_{s, U, s} R & \xrightarrow{(r_0, r_1) \mapsto r_0 \circ r_1^{-1}} & R \\
\text{pr}_0 \downarrow & & \downarrow t \\
R & \xrightarrow{t} & U
\end{array}$$

we see that $R \times_{s, U, s} R$ has the universal property of a colimit of $s^* \mathcal{G}$ in the category of quasi-coherent modules on $(U, R, s, t, c)$. Hence $\text{Qcoh}(O_U)$ has the universal property of a colimit of $\mathcal{G}$ in the category of quasi-coherent modules on $(U, R, s, t, c)$ as desired. \hfill $\square$
by Lemma 13.5 it follows that Lemma 14.4 applies to \( f \). Note that
\[
\text{QCoh}(R, R \times_{s,U} R, \text{pr}_1, \text{pr}_0, \text{pr}_{02}) = \text{QCoh}(\mathcal{O}_U)
\]
by the theory of descent of quasi-coherent sheaves as \( \{ t : R \to U \} \) is an fpqc covering, see Descent, Proposition 5.2. Observe that pullback along \( f \) agrees with the forgetful functor and that pushforward agrees with the construction that assigns to \( G \) the pair \((G, \alpha)\). We omit the precise verifications. Thus the lemma follows from Lemma 14.4.

\[\square\]

**Lemma 15.2.** Let \( f : Y \to X \) be a morphism of schemes. Let \( F \) be a quasi-coherent \( \mathcal{O}_X \)-module, let \( G \) be a quasi-coherent \( \mathcal{O}_Y \)-module, and let \( \varphi : G \to f^*F \) be a module map. Assume

1. \( \varphi \) is injective,
2. \( f \) is quasi-compact, quasi-separated, flat, and surjective,
3. \( X, Y \) are locally Noetherian, and
4. \( G \) is a coherent \( \mathcal{O}_Y \)-module.

Then \( F \cap f_*G \) defined as the pullback

\[
\begin{array}{ccc}
F & \longrightarrow & f_*f^*F \\
\downarrow & & \downarrow \\
F \cap f_*G & \longrightarrow & f_*G
\end{array}
\]

is a coherent \( \mathcal{O}_X \)-module.

**Proof.** We will freely use the characterization of coherent modules of Cohomology of Schemes, Lemma 9.1 as well as the fact that coherent modules form a Serre subcategory of \( \text{QCoh}(\mathcal{O}_X) \), see Cohomology of Schemes, Lemma 9.3. If \( f \) has a section \( \sigma \), then we see that \( F \cap f_*G \) is contained in the image of \( \sigma^*G \to \sigma^*f^*F = F \), hence coherent. In general, to show that \( F \cap f_*G \) is coherent, it suffices the show that \( f^*(F \cap f_*G) \) is coherent (see Descent, Lemma 7.1). Since \( f \) is flat this is equal to \( f^*F \cap f^*f_*G \). Since \( f \) is flat, quasi-compact, and quasi-separated we see \( f^*f_*G = q_*q^*G \) where \( p,q : Y \times_X Y \to Y \) are the projections, see Cohomology of Schemes, Lemma 5.2. Since \( p \) has a section we win.  \[\square\]

Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid in schemes over \( S \). Assume that \( U \) is locally Noetherian. In the lemma below we say that a quasi-coherent sheaf \((F, \alpha)\) on \((U, R, s, t, c)\) is coherent if \( F \) is a coherent \( \mathcal{O}_U \)-module.

**Lemma 15.3.** Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \). Assume that

1. \( U, R \) are Noetherian,
2. \( s, t \) are flat, quasi-compact, and quasi-separated.

Then every quasi-coherent module \((F, \alpha)\) on \((U, R, s, t, c)\) is a filtered colimit of coherent modules.

**Proof.** We will use the characterization of Cohomology of Schemes, Lemma 9.1 of coherent modules on locally Noetherian scheme without further mention. Write \( F = \text{colim} \mathcal{H}_i \) with \( \mathcal{H}_i \) coherent, see Properties, Lemma 22.6. Given a quasi-coherent sheaf \( \mathcal{H} \) on \( U \) we denote \( t_*s^*\mathcal{H} \) the quasi-coherent sheaf on \((U, R, s, t, c)\)
of Lemma [15.1] There is an adjunction map $F \to t_* s^* F$ in $QCoh(U, R, s, t, c)$. Consider the pullback diagram

\[
\begin{array}{ccc}
F & \to & t_* s^* F \\
\uparrow & & \uparrow \\
F_i & \to & t_* s^* H_i
\end{array}
\]

in other words $F_i = F \cap t_* s^* H_i$. Then $F_i$ is coherent by Lemma [15.2]. On the other hand, the diagram above is a pullback diagram in $QCoh(U, R, s, t, c)$ also as restriction to $U$ is an exact functor by (the proof of) Lemma [14.6]. Finally, because $t$ is quasi-compact and quasi-separated we see that $t_*$ commutes with colimits (see Cohomology of Schemes, Lemma [6.1]). Hence $t_* s^* F = \text{colim} t_* H_i$ and hence $F = \text{colim} F_i$ as desired. □

Here is a curious lemma that is useful when working with groupoids on fields. In fact, this is the standard argument to prove that any representation of an algebraic group is a colimit of finite dimensional representations.

**Lemma 15.4.** Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume that

1. $U$, $R$ are affine,
2. there exist $e_i \in O_R(R)$ such that every element $g \in O_R(R)$ can be uniquely written as $\sum s^*(f_i) e_i$ for some $f_i \in O_U(U)$.

Then every quasi-coherent module $(F, \alpha)$ on $(U, R, s, t, c)$ is a filtered colimit of finite type quasi-coherent modules.

**Proof.** The assumption means that $O_R(R)$ is a free $O_U(U)$-module via $s$ with basis $e_i$. Hence for any quasi-coherent $O_U(U)$-module $G$ we see that $s^* G(R) = \bigoplus_i G(U) e_i$. We will write $s(-)$ to indicate pullback of sections by $s$ and similarly for other morphisms. Let $(F, \alpha)$ be a quasi-coherent module on $(U, R, s, t, c)$. Let $\sigma \in F(U)$. By the above we can write

$$\alpha(t(\sigma)) = \sum s(\sigma_i) e_i$$

for some unique $\sigma_i \in F(U)$ (all but finitely many are zero of course). We can also write

$$c(e_i) = \sum \text{pr}_1(f_{ij}) \text{pr}_0(e_j)$$

as functions on $R \times_{s, U, t} R$. Then the commutativity of the diagram in Definition [14.1] means that

$$\sum \text{pr}_1(\alpha(t(\sigma_i))) \text{pr}_0(e_i) = \sum \text{pr}_1(s(\sigma_i) f_{ij}) \text{pr}_0(e_j)$$

(calculation omitted). Picking off the coefficients of $\text{pr}_0(e_i)$ we see that $\alpha(t(\sigma_i)) = \sum s(\sigma_i) f_{ij}$. Hence the submodule $G \subset F$ generated by the elements $\sigma_i$ defines a finite type quasi-coherent module preserved by $\alpha$. Hence it is a subobject of $F$ in $QCoh(U, R, s, t, c)$. This submodule contains $\sigma$ (as one sees by pulling back the first relation by $e$). Hence we win. □

We suggest the reader skip the rest of this section. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid in schemes over $S$. Let $\kappa$ be a cardinal. In the following we will say that a quasi-coherent sheaf $(F, \alpha)$ on $(U, R, s, t, c)$ is $\kappa$-generated if $F$ is a $\kappa$-generated $O_U$-module, see Properties, Definition [23.1].
Lemma 15.5. Let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). Let \(\kappa\) be a cardinal. There exists a set \(T\) and a family \((\mathcal{F}_t, \alpha_t)_{t \in T}\) of \(\kappa\)-generated quasi-coherent modules on \((U, R, s, t, c)\) such that every \(\kappa\)-generated quasi-coherent module on \((U, R, s, t, c)\) is isomorphic to one of the \((\mathcal{F}_t, \alpha_t)\).

**Proof.** For each quasi-coherent module \(\mathcal{F}\) on \(U\) there is a (possibly empty) set of maps \(\alpha : t^* \mathcal{F} \to s^* \mathcal{F}\) such that \((\mathcal{F}, \alpha)\) is a quasi-coherent module on \((U, R, s, t, c)\).

By Properties, Lemma 23.2 there exists a set of isomorphism classes of \(\kappa\)-generated quasi-coherent \(\mathcal{O}_U\)-modules. \(\square\)

Lemma 15.6. Let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). Assume that \(s, t\) are flat. There exists a cardinal \(\kappa\) such that every quasi-coherent module \((\mathcal{F}, \alpha)\) on \((U, R, s, t, c)\) is the directed colimit of its \(\kappa\)-generated quasi-coherent submodules.

**Proof.** In the statement of the lemma and in this proof a submodule of a quasi-coherent module \((\mathcal{F}, \alpha)\) is a quasi-coherent submodule \(\mathcal{G} \subset \mathcal{F}\) such that \(\alpha(t^* \mathcal{G}) = s^* \mathcal{G}\) as subsheaves of \(s^* \mathcal{F}\). This makes sense because since \(s, t\) are flat the pullbacks \(s^*\) and \(t^*\) are exact, i.e., preserve subsheaves. The proof will be a repeat of the proof of Properties, Lemma 23.3. We urge the reader to read that proof first.

Choose an affine open covering \(U = \bigcup_{i \in I} U_i\). For each pair \(i, j\) choose affine open coverings

\[
U_i \cap U_j = \bigcup_{k \in I_{ij}} U_{ijk} \quad \text{and} \quad s^{-1}(U_i) \cap t^{-1}(U_j) = \bigcup_{k \in J_{ij}} W_{ijk}.
\]

Write \(U_i = \text{Spec}(A_i)\), \(U_{ijk} = \text{Spec}(A_{ijk})\), \(W_{ijk} = \text{Spec}(B_{ijk})\). Let \(\kappa\) be any infinite cardinal \(\geq\) than the cardinality of any of the sets \(I, I_{ij}, J_{ij}\).

Let \((\mathcal{F}, \alpha)\) be a quasi-coherent module on \((U, R, s, t, c)\). Set \(M_i = \mathcal{F}(U_i)\), \(M_{ijk} = \mathcal{F}(U_{ijk})\). Note that

\[
M_i \otimes_{A_i} A_{ijk} = M_{ijk} = M_j \otimes_{A_j} A_{ijk}
\]

and that \(\alpha\) gives isomorphisms

\[
\alpha|_{W_{ijk}} : M_i \otimes_{A_i, t} B_{ijk} \to M_j \otimes_{A_j, s} B_{ijk}
\]

see Schemes, Lemma 7.3. Using the axiom of choice we choose a map

\[
(i, j, k, m) \mapsto S(i, j, k, m)
\]

which associates to every \(i, j \in I, k \in I_{ij}\) or \(k \in J_{ij}\) and \(m \in M_i\) a finite subset \(\mathcal{S}(i, j, k, m) \subset M_j\) such that we have

\[
m \otimes 1 = \sum_{m' \in \mathcal{S}(i, j, k, m)} m' \otimes a_{m'} \quad \text{or} \quad \alpha(m \otimes 1) = \sum_{m' \in \mathcal{S}(i, j, k, m)} m' \otimes b_{m'}
\]

in \(M_{ijk}\) for some \(a_{m'} \in A_{ijk}\) or \(b_{m'} \in B_{ijk}\). Moreover, let’s agree that \(\mathcal{S}(i, j, k, m) = \{m\}\) for all \(i, j = i, k, m\) when \(k \in I_{ij}\). Fix such a collection \(\mathcal{S}(i, j, k, m)\).

Given a family \(\mathcal{S} = (\mathcal{S}_i)_{i \in I}\) of subsets \(\mathcal{S}_i \subset M_i\) of cardinality at most \(\kappa\) we set

\[
\mathcal{S}' = (\mathcal{S}'_i)
\]

where

\[
\mathcal{S}'_j = \bigcup_{(i, j, k, m) \text{ such that } m \in \mathcal{S}_i} S(i, j, k, m)
\]

Note that \(\mathcal{S}_i \subset \mathcal{S}'_i\). Note that \(\mathcal{S}'_i\) has cardinality at most \(\kappa\) because it is a union over a set of cardinality at most \(\kappa\) of finite sets. Set \(\mathcal{S}^{(0)} = \mathcal{S}, \mathcal{S}^{(1)} = \mathcal{S}'\) and by induction \(\mathcal{S}^{(n+1)} = (\mathcal{S}^{(n)})'\). Then set \(\mathcal{S}^{(\infty)} = \bigcup_{n \geq 0} \mathcal{S}^{(n)}\). Writing \(\mathcal{S}^{(\infty)} = (\mathcal{S}'_i^{(\infty)})\)
we see that for any element $m \in S^\infty_g$ the image of $m$ in $M_{ijk}$ can be written as a finite sum $\sum m' \otimes a_{m'}$ with $m' \in S^\infty_f$. In this way we see that setting

$$N_i = A_i \text{-submodule of } M_i \text{ generated by } S^\infty_i$$

we have

$$N_i \otimes_{A_i} A_{ijk} = N_j \otimes_{A_j} A_{ijk} \quad \text{and} \quad \alpha(N_i \otimes_{A_i,t} B_{ijk}) = N_j \otimes_{A_j,s} B_{ijk}$$
as submodules of $M_{ijk}$ or $M_j \otimes_{A_j,s} B_{ijk}$. Thus there exists a quasi-coherent submodule $\mathcal{G} \subseteq \mathcal{F}$ with $\mathcal{G}(U_i) = N_i$ such that $\alpha(t^* \mathcal{G}) = s^* \mathcal{G}$ as submodules of $s^* \mathcal{F}$. In other words, $(\mathcal{G}, \alpha_{(t^* \mathcal{G})})$ is a submodule of $(\mathcal{F}, \alpha)$. Moreover, by construction $\mathcal{G}$ is $\kappa$-generated.

Let $\{(\mathcal{G}_t, \alpha_t)\}_{t \in T}$ be the set of $\kappa$-generated quasi-coherent submodules of $(\mathcal{F}, \alpha)$. If $t, t' \in T$ then $\mathcal{G}_t \oplus \mathcal{G}_{t'}$ is also a $\kappa$-generated quasi-coherent submodule as it is the image of the map $\mathcal{G}_t \oplus \mathcal{G}_{t'} \to \mathcal{F}$. Hence the system (ordered by inclusion) is directed. The arguments above show that every section of $\mathcal{F}$ over $U_i$ is in one of the $\mathcal{G}_i$ (because we can start with $\mathcal{S}$ such that the given section is an element of $S_i$). Hence colim $\mathcal{G}_i \to \mathcal{F}$ is both injective and surjective as desired. \qed

16. Groupoids and group schemes

There are many ways to construct a groupoid out of an action $a$ of a group $G$ on a set $V$. We choose the one where we think of an element $g \in G$ as an arrow with source $v$ and target $a(g, v)$. This leads to the following construction for group actions of schemes.

Lemma 16.1. Let $S$ be a scheme. Let $Y$ be a scheme over $S$. Let $(G, m)$ be a group scheme over $Y$ with identity $e_G$ and inverse $i_G$. Let $X/Y$ be a scheme over $Y$ and let $a : G \times_Y X \to X$ be an action of $G$ on $X/Y$. Then we get a groupoid scheme $(U, R, s, t, c, e, i)$ over $S$ in the following manner:

1. We set $U = X$, and $R = G \times_Y X$.
2. We set $s : R \to U$ equal to $(g, x) \mapsto x$.
3. We set $t : R \to U$ equal to $(g, x) \mapsto a(g, x)$.
4. We set $c : R \times_U t R \to R$ equal to $((g, x), (g', x')) \mapsto (m(g, g'), x')$.
5. We set $e : U \to R$ equal to $x \mapsto (e_G(x), x)$.
6. We set $i : R \to R$ equal to $(g, x) \mapsto (i_G(g), a(g, x))$.

Proof. Omitted. Hint: It is enough to show that this works on the set level. For this use the description above the lemma describing $g$ as an arrow from $v$ to $a(g, v)$. \qed

Lemma 16.2. Let $S$ be a scheme. Let $Y$ be a scheme over $S$. Let $(G, m)$ be a group scheme over $Y$. Let $X$ be a scheme over $Y$ and let $a : G \times_Y X \to X$ be an action of $G$ on $X$ over $Y$. Let $(U, R, s, t, c)$ be the groupoid scheme constructed in Lemma 16.1. The rule $(\mathcal{F}, \alpha) \mapsto (\mathcal{F}, \alpha)$ defines an equivalence of categories between $G$-equivariant $\mathcal{O}_X$-modules and the category of quasi-coherent modules on $(U, R, s, t, c)$.

Proof. The assertion makes sense because $t = a$ and $s = \text{pr}_1$ as morphisms $R = G \times_Y X \to X$, see Definitions [12.1 and 14.1] Using the translation in Lemma 16.1 the commutativity requirements of the two definitions match up exactly. \qed
17. The stabilizer group scheme

Given a groupoid scheme we get a group scheme as follows.

\textbf{Lemma 17.1.} Let \(S\) be a scheme. Let \((U, R, s, t, c)\) be a groupoid over \(S\). The scheme \(G\) defined by the cartesian square

\[
\begin{array}{ccc}
G & \rightarrow & R \\
\downarrow & & \downarrow \mathrlap{j=(t,s)} \\
U & \xrightarrow{\Delta} & U \times_S U
\end{array}
\]

is a group scheme over \(U\) with composition law \(m\) induced by the composition law \(c\).

\textbf{Proof.} This is true because in a groupoid category the set of self maps of any object forms a group. \(\square\)

Since \(\Delta\) is an immersion we see that \(G = j^{-1}(\Delta_{U/S})\) is a locally closed subscheme of \(R\). Thinking of it in this way, the structure morphism \(j^{-1}(\Delta_{U/S}) \rightarrow U\) is induced by either \(s\) or \(t\) (it is the same), and \(m\) is induced by \(c\).

\textbf{Definition 17.2.} Let \(S\) be a scheme. Let \((U, R, s, t, c)\) be a groupoid over \(S\). The group scheme \(j^{-1}(\Delta_{U/S}) \rightarrow U\) is called the \textit{stabilizer of the groupoid scheme} \((U, R, s, t, c)\).

In the literature the stabilizer group scheme is often denoted \(S\) (because the word stabilizer starts with an “s” presumably); we cannot do this since we have already used \(S\) for the base scheme.

\textbf{Lemma 17.3.} Let \(S\) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \(S\), and let \(G/U\) be its stabilizer. Denote \(R_t/U\) the scheme \(R\) seen as a scheme over \(U\) via the morphism \(t : R \rightarrow U\). There is a canonical left action

\[a : G \times_U R_t \rightarrow R_t\]

induced by the composition law \(c\).

\textbf{Proof.} In terms of points over \(T/S\) we define \(a(g, r) = c(g, r)\). \(\square\)

\textbf{Lemma 17.4.} Let \(S\) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). Let \(G\) be the stabilizer group scheme of \(R\). Let

\[G_0 = G \times_{U, pr_0} (U \times_S U) = G \times_S U\]

as a group scheme over \(U \times_S U\). The action of \(G\) on \(R\) of Lemma 17.3 induces an action of \(G_0\) on \(R\) over \(U \times_S U\) which turns \(R\) into a pseudo \(G_0\)-torsor over \(U \times_S U\).

\textbf{Proof.} This is true because in a groupoid category \(\mathcal{C}\) the set \(\text{Mor}_{\mathcal{C}}(x, y)\) is a principal homogeneous set under the group \(\text{Mor}_{\mathcal{C}}(y, y)\). \(\square\)

\textbf{Lemma 17.5.} Let \(S\) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \(S\). Let \(p \in U \times_S U\) be a point. Denote \(R_p\) the scheme theoretic fibre of \(j = (t, s) : R \rightarrow U \times_S U\). If \(R_p \neq \emptyset\), then the action

\[G_{0, \kappa(p)} \times_{\kappa(p)} R_p \rightarrow R_p\]

(see Lemma 17.4) which turns \(R_p\) into a \(G_{\kappa(p)}\)-torsor over \(\kappa(p)\).
Proof. The action is a pseudo-torsor by the lemma cited in the statement. And if $R_p$ is not the empty scheme, then $\{R_p \to p\}$ is an fpqc covering which trivializes the pseudo-torsor.

18. Restricting groupoids

02VA Consider a (usual) groupoid $C = (\text{Ob}, \text{Arrows}, s, t, c)$. Suppose we have a map of sets $g : \text{Ob}' \to \text{Ob}$. Then we can construct a groupoid $C' = (\text{Ob}', \text{Arrows}', s', t', c')$ by thinking of a morphism between elements $x', y'$ of $\text{Ob}'$ as a morphism in $C$ between $g(x'), g(y')$. In other words we set

\[
\text{Arrows}' = \text{Ob}' \times_{g, \text{Ob}, g} \text{Arrows} \times_{s, \text{Ob}, g} \text{Ob}'
\]

with obvious choices for $s'$, $t'$, and $c'$. There is a canonical functor $C' \to C$ which is fully faithful, but not necessarily essentially surjective. This groupoid $C'$ endowed with the functor $C' \to C$ is called the restriction of the groupoid $C$ to $\text{Ob}'$.

Lemma 18.1. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Let $g : U' \to U$ be a morphism of schemes. Consider the following diagram

\[
\begin{array}{cccccc}
R' & \xrightarrow{s'} & U' & \xrightarrow{g} & U \\
\downarrow & & \downarrow & & \downarrow \\
\downarrow & & \downarrow & & \downarrow \\
R & \xrightarrow{s, U} & U' & \xrightarrow{U \times_{U', t} R} & R & \xrightarrow{t} & U \\
\end{array}
\]

where all the squares are fibre product squares. Then there is a canonical composition law $c' : R' \times_{s', U', t'} R' \to R'$ such that $(U', R', s', t', c')$ is a groupoid scheme over $S$ and such that $U' \to U$, $R' \to R$ defines a morphism $(U', R', s', t', c') \to (U, R, s, t, c)$ of groupoid schemes over $S$. Moreover, for any scheme $T$ over $S$ the functor of groupoids $(U', R', s', t', c') \to (U(T), R(T), s, t, c)$ is the restriction (see above) of $(U(T), R(T), s, t, c)$ via the map $U'(T) \to U(T)$.

Proof. Omitted.

02VB Lemma 18.2. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Let $g : U' \to U$ be a morphism of schemes. The morphism of groupoids $(U', R', s', t', c') \to (U, R, s, t, c)$ constructed in Lemma 18.1 is called the restriction of $(U, R, s, t, c)$ to $U'$. We sometime use the notation $R' = R|_{U'}$ in this case.

02VC Definition 18.3. The notions of restricting groupoids and (pre-)equivalence relations defined in Definitions 18.2 and 3.3 agree via the constructions of Lemmas 13.2 and 13.3.

Proof. What we are saying here is that $R'$ of Lemma 18.1 is also equal to

\[
R' = (U' \times_{S} U') \times_{U \times_{U'} U} R \to U' \times_{S} U'
\]

In fact this might have been a clearer way to state that lemma.
Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \). Let \( g: U' \to U \) be a morphism of schemes. Let \((U', R', s', t', c')\) be the restriction of \((U, R, s, t, c)\) via \( g \). Let \( G \) be the stabilizer of \((U, R, s, t, c)\) and let \( G' \) be the stabilizer of \((U', R', s', t', c')\). Then \( G' \) is the base change of \( G \) by \( g \), i.e., there is a canonical identification \( G' = U' \times_{g, U} G \).

**Proof.** Omitted. \( \square \)

19. Invariant subschemes

In this section we discuss briefly the notion of an invariant subscheme.

**Definition 19.1.** Let \((U, R, s, t, c)\) be a groupoid scheme over the base scheme \( S \).

1. A subset \( W \subset U \) is set-theoretically \( R \)-invariant if \( t(s^{-1}(W)) \subset W \).
2. An open \( W \subset U \) is \( R \)-invariant if \( t(s^{-1}(W)) \subset W \).
3. A closed subscheme \( Z \subset U \) is called \( R \)-invariant if \( t^{-1}(Z) = s^{-1}(Z) \). Here we use the scheme theoretic inverse image, see Schemes, Definition 17.7.
4. A monomorphism of schemes \( T \to U \) is \( R \)-invariant if \( T \times_{U, t} R = R \times_{s, U} T \) as schemes over \( R \).

For subsets and open subschemes \( W \subset U \) the \( R \)-invariance is also equivalent to requiring that \( s^{-1}(W) = t^{-1}(W) \) as subsets of \( R \). If \( W \subset U \) is an \( R \)-equivariant open subscheme then the restriction of \( R \) to \( W \) is just \( R_W = s^{-1}(W) = t^{-1}(W) \). Similarly, if \( Z \subset U \) is an \( R \)-invariant closed subscheme, then the restriction of \( R \) to \( Z \) is just \( R_Z = s^{-1}(Z) = t^{-1}(Z) \).

**Lemma 19.2.** Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \).

1. For any subset \( W \subset U \) the subset \( t(s^{-1}(W)) \) is set-theoretically \( R \)-invariant.
2. If \( s \) and \( t \) are open, then for every open \( W \subset U \) the open \( t(s^{-1}(W)) \) is an \( R \)-invariant open subscheme.
3. If \( s \) and \( t \) are open and quasi-compact, then \( U \) has an open covering consisting of \( R \)-invariant quasi-compact open subschemes.

**Proof.** Part (1) follows from Lemmas 3.4 and 13.2 namely, \( t(s^{-1}(W)) \) is the set of points of \( U \) equivalent to a point of \( W \). Next, assume \( s \) and \( t \) open and \( W \subset U \) open. Since \( s \) is open the set \( W' = t(s^{-1}(W)) \) is an open subset of \( U \). Finally, assume that \( s \), \( t \) are both open and quasi-compact. Then, if \( W \subset U \) is a quasi-compact open, then also \( W' = t(s^{-1}(W)) \) is a quasi-compact open, and invariant by the discussion above. Letting \( W \) range over all affine opens of \( U \) we see (3). \( \square \)

**Lemma 19.3.** Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \). Assume \( s \) and \( t \) quasi-compact and flat and \( U \) quasi-separated. Let \( W \subset U \) be quasi-compact open. Then \( t(s^{-1}(W)) \) is an intersection of a nonempty family of quasi-compact open subsets of \( U \).

**Proof.** Note that \( s^{-1}(W) \) is quasi-compact open in \( R \). As a continuous map \( t \) maps the quasi-compact subset \( s^{-1}(W) \) to a quasi-compact subset \( t(s^{-1}(W)) \). As \( t \) is flat and \( s^{-1}(W) \) is closed under generalization, so is \( t(s^{-1}(W)) \), see (Morphisms, Lemma 24.8 and Topology, Lemma 19.6). Pick a quasi-compact open \( W' \subset U \) containing \( t(s^{-1}(W)) \). By Properties, Lemma 2.4 we see that \( W' \) is a spectral space (here we use that \( U \) is quasi-separated). Then the lemma follows from Topology, Lemma 24.7 applied to \( t(s^{-1}(W)) \subset W' \). \( \square \)
Lemma 19.4. Assumptions and notation as in Lemma 19.3. There exists an $R$-invariant open $V \subset U$ and a quasi-compact open $W'$ such that $W \subset V \subset W' \subset U$.

Proof. Set $E = t(s^{-1}(W))$. Recall that $E$ is set-theoretically $R$-invariant (Lemma 19.2). By Lemma 19.3 there exists a quasi-compact open $W'$ containing $E$. Let $Z = U \setminus W'$ and consider $T = t(s^{-1}(Z))$. Observe that $Z \subset T$ and that $E \cap T = \emptyset$ because $s^{-1}(E) = t^{-1}(E)$ is disjoint from $s^{-1}(Z)$. Since $T$ is the image of the closed subset $s^{-1}(Z) \subset R$ under the quasi-compact morphism $t : R \to U$ we see that any point $\xi$ in the closure $\overline{T}$ is the specialization of a point of $T$, see Morphisms, Lemma 6.5 (and Morphisms, Lemma 6.3 to see that the scheme theoretic image $s(r)$ is the closure of the image). Say $\xi' \leadsto \xi$ with $\xi' \in T$. Suppose that $r \in R$ and $s(r) = \xi$. Since $s$ is flat we can find a specialization $r' \leadsto r$ in $R$ such that $s(r') = \xi'$ (Morphisms, Lemma 24.8). Then $t(r') \leadsto t(r)$. We conclude that $t(r') \in T$ as $T$ is set-theoretically invariant by Lemma 19.2. Thus $\overline{T}$ is a set-theoretically $R$-invariant closed subset and $V = U \setminus \overline{T}$ is the open we are looking for. It is contained in $W'$ which finishes the proof.

20. Quotient sheaves

Let $\tau \in \{\text{Zariski, étale, fppf, smooth, syntomic}\}$. Let $S$ be a scheme. Let $j : R \to U \times_S U$ be a pre-relation over $S$. Say $U, R, S$ are objects of a $\tau$-site $\text{Sch}_\tau$ (see Topologies, Section 2). Then we can consider the functors

$$h_U, h_R : (\text{Sch}/S)_\tau^{\text{op}} \to \text{Sets}.$$  

These are sheaves, see Descent, Lemma 10.7. The morphism $j$ induces a map $j : h_R \to h_U \times h_U$. For each object $T \in \text{Ob}(\text{Sch}/S)_\tau$ we can take the equivalence relation $\sim_T$ generated by $j(T) : R(T) \to U(T) \times U(T)$ and consider the quotient. Hence we get a presheaf

$$(\text{Sch}/S)_\tau^{\text{op}} \to \text{Sets}, \ T \mapsto U(T)/\sim_T.$$  

Definition 20.1. Let $\tau, S$, and the pre-relation $j : R \to U \times_S U$ be as above. In this setting the quotient sheaf $U/R$ associated to $j$ is the sheafification of the presheaf (20.0.1) in the $\tau$-topology. If $j : R \to U \times_S U$ comes from the action of a group scheme $G/S$ on $U$ as in Lemma 16.1 then we sometimes denote the quotient sheaf $U/G$.

This means exactly that the diagram

$$h_R \xrightarrow{j} h_U \to U/R$$

is a coequalizer diagram in the category of sheaves of sets on $(\text{Sch}/S)_\tau$. Using the Yoneda embedding we may view $(\text{Sch}/S)_\tau$ as a full subcategory of sheaves on $(\text{Sch}/S)_\tau$ and hence identify schemes with representable functors. Using this abuse of notation we will often depict the diagram above simply

$$R \xrightarrow{s} U \to U/R.$$  

We will mostly work with the fppf topology when considering quotient sheaves of groupoids/equivalence relations.
Definition 20.2. In the situation of Definition 20.1, we say that the pre-relation \( j \) has a \textit{representable quotient} if the sheaf \( U/R \) is representable. We will say a groupoid \((U,R,s,t,c)\) has a \textit{representable quotient} if the quotient \( U/R \) with \( j = (t,s) \) is representable.

The following lemma characterizes schemes \( M \) representing the quotient. It applies for example if \( \tau = fppf \), \( U \to M \) is flat, of finite presentation and surjective, and \( R \cong U \times_M U \).

Lemma 20.3. In the situation of Definition 20.1. Assume there is a scheme \( M \), and a morphism \( U \to M \) such that

1. the morphism \( U \to M \) equalizes \( s,t \),
2. the morphism \( U \to M \) induces a surjection of sheaves \( h_U \to h_M \) in the \( \tau \)-topology, and
3. the induced map \( (t,s) : R \to U \times_M U \) induces a surjection of sheaves \( h_R \to h_{U \times_M U} \) in the \( \tau \)-topology.

In this case \( M \) represents the quotient sheaf \( U/R \).

Proof. Condition (1) says that \( h_U \to h_M \) factors through \( U/R \). Condition (2) says that \( U/R \to h_M \) is surjective as a map of sheaves. Condition (3) says that \( U/R \to h_M \) is injective as a map of sheaves. Hence the lemma follows. □

The following lemma is wrong if we do not require \( j \) to be a pre-equivalence relation (but just a pre-relation say).

Lemma 20.4. Let \( \tau \in \{ \text{Zariski, étale, fppf, smooth, syntomic} \} \). Let \( S \) be a scheme. Let \( j : R \to U \times_S U \) be a pre-equivalence relation over \( S \). Assume \( U,R,S \) are objects of a \( \tau \)-site \( \text{Sch}_\tau \). For \( T \in \text{Ob}(\text{Sch}/S)_\tau \) and \( a,b \in U(T) \) the following are equivalent:

1. \( a \) and \( b \) map to the same element of \( (U/R)(T) \), and
2. there exists a \( \tau \)-covering \( \{ f_i : T_i \to T \} \) of \( T \) and morphisms \( r_i : T_i \to R \) such that \( a \circ f_i = s \circ r_i \) and \( b \circ f_i = t \circ r_i \).

In other words, in this case the map of \( \tau \)-sheaves

\[ h_R \to h_{U \times_U R} h_U \]

is surjective.

Proof. Omitted. Hint: The reason this works is that the presheaf (20.0.1) in this case is really given by \( T \mapsto U(T)/j(R(T)) \) as \( j(R(T)) \subset U(T) \times_U U(T) \) is an equivalence relation, see Definition 3.1. □

Lemma 20.5. Let \( \tau \in \{ \text{Zariski, étale, fppf, smooth, syntomic} \} \). Let \( S \) be a scheme. Let \( j : R \to U \times_S U \) be a pre-equivalence relation over \( S \) and \( g : U' \to U \) a morphism of schemes over \( S \). Let \( j' : R' \to U' \times_S U' \) be the restriction of \( j \) to \( U' \). Assume \( U,U',R,S \) are objects of a \( \tau \)-site \( \text{Sch}_\tau \). The map of quotient sheaves

\[ U'/R' \to U/R \]

is injective. If \( g \) defines a surjection \( h_{U'} \to h_U \) of sheaves in the \( \tau \)-topology (for example if \( \{ g : U' \to U \} \) is a \( \tau \)-covering), then \( U'/R' \to U/R \) is an isomorphism.
**Proof.** Suppose \( \xi, \xi' \in (U'/R')(T) \) are sections which map to the same section of \( U/R \). Then we can find a \( \tau \)-covering \( \mathcal{T} = \{ T_i \to T \} \) of \( T \) such that \( \xi|_{T_i}, \xi'|_{T_i} \), are given by \( a_i, a'_i \in U'(T_i) \). By Lemma 20.4 and the axioms of a site we may after refining \( \mathcal{T} \) assume there exist morphisms \( r_i : T_i \to R \) such that \( g \circ a_i = s \circ r_i \), \( g \circ a'_i = t \circ r_i \). Since by construction \( R' = R \times_{U \times S} U' \times_{S} U'' \) we see that \( (r_i, (a_i, a'_i)) \in R'(T_i) \) and this shows that \( a_i \) and \( a'_i \) define the same section of \( U'/R' \) over \( T_i \). By the sheaf condition this implies \( \xi = \xi' \).

If \( h_{U'} \to h_U \) is a surjection of sheaves, then of course \( U'/R' \to U/R \) is surjective also. If \( \{ g : U' \to U \} \) is a \( \tau \)-covering, then the map of sheaves \( h_{U'} \to h_U \) is surjective, see Sites, Lemma 12.4. Hence \( U'/R' \to U/R \) is surjective also in this case. \( \square \)

**Lemma 20.6.** Let \( \tau \in \{ \text{Zariski, étale, fppf, smooth, syntomic} \} \). Let \( S \) be a scheme. Let \( (U, R, s, t, c) \) be a groupoid scheme over \( S \). Let \( g : U' \to U \) a morphism of schemes over \( S \). Let \( (U', R', s', t', c') \) be the restriction of \( (U, R, s, t, c) \) to \( U' \).

Assume \( U, U', R, S \) are objects of a \( \tau \)-site \( \mathcal{S}_{+} \). The map of quotient sheaves

\[
U'/R' \to U/R
\]

is injective. If the composition

\[
U' \times_{g, U, t} R \xrightarrow{h} R \xrightarrow{\text{pr}_s} U
\]

defines a surjection of sheaves in the \( \tau \)-topology then the map is bijective. This holds for example if \( \{ h : U' \times_{g, U, t} R \to U \} \) is a \( \tau \)-covering, or if \( U' \to U \) defines a surjection of sheaves in the \( \tau \)-topology, or if \( \{ g : U' \to U \} \) is a covering in the \( \tau \)-topology.

**Proof.** Injectivity follows on combining Lemmas 13.2 and 20.5. To see surjectivity (see Sites, Section 11 for a characterization of surjective maps of sheaves) we argue as follows. Suppose that \( T \) is a scheme and \( \sigma \in U/R(T) \). There exists a covering \( \{ T_i \to T \} \) such that \( \sigma|_{T_i} \) is the image of some element \( f_i \in U(T_i) \). Hence we may assume that \( \sigma \) is the image of \( f \in U(T) \). By the assumption that \( h \) is a surjection of sheaves, we can find a \( \tau \)-covering \( \{ \varphi_i : T_i \to T \} \) and morphisms \( f_i : T_i \to U' \times_{g, U, t} R \) such that \( g \circ \varphi_i = h \circ f_i \). Denote \( f_i' = \text{pr}_g \circ f_i : T_i \to U' \). Then we see that \( f_i' \in U'(T_i) \) maps to \( g \circ f_i' \in U(T_i) \) and that \( g \circ f_i' \sim_{T_i} h \circ f_i \) notation as in 20.0.1. Namely, the element of \( R(T_i) \) giving the relation is \( \text{pr}_r \circ f_i \). This means that the restriction of \( \sigma \) to \( T_i \) is in the image of \( U'/R'(T_i) \to U/R(T_i) \) as desired.

If \( \{ h \} \) is a \( \tau \)-covering, then it induces a surjection of sheaves, see Sites, Lemma 12.4. If \( U' \to U \) is surjective, then also \( h \) is surjective as \( s \) has a section (namely the neutral element \( e \) of the groupoid scheme). \( \square \)

**Lemma 20.7.** Let \( S \) be a scheme. Let \( f : (U, R, j) \to (U', R', j') \) be a morphism between equivalence relations over \( S \). Assume that

\[
\begin{array}{ccc}
R & \xrightarrow{f} & R' \\
\downarrow{s} & & \downarrow{s'} \\
U & \xrightarrow{f} & U'
\end{array}
\]
is cartesian. For any \( \tau \in \{ \text{Zariski, étale, fppf, smooth, syntomic} \} \) the diagram

\[
\begin{array}{ccc}
U & \rightarrow & U/R \\
\downarrow & & \downarrow f \\
U' & \rightarrow & U'/R'
\end{array}
\]

is a fibre product square of \( \tau \)-sheaves.

**Proof.** By Lemma 20.4 the quotient sheaves have a simple description which we will use below without further mention. We first show that \( U \rightarrow U' \times_{U'/R'} U/R \) is injective. Namely, assume \( a, b \in U(T) \) map to the same element on the right hand side. Then \( f(a) = f(b) \). After replacing \( T \) by the members of a \( \tau \)-covering we may assume that there exists an \( r \in R(T) \) such that \( a = s(r) \) and \( b = t(r) \). Then \( r' = f(r) \) is a \( T \)-valued point of \( R' \) with \( s'(r') = t'(r') \). Hence \( r' = e'(f(a)) \) (where \( e' \) is the identity of the groupoid scheme associated to \( j' \), see Lemma 13.3). Because the first diagram of the lemma is cartesian this implies that \( r \) has to equal \( e(a) \). Thus \( a = b \).

Finally, we show that the displayed arrow is surjective. Let \( T \) be a scheme over \( S \) and let \((a', b)\) be a section of the sheaf \( U' \times_{U'/R'} U/R \) over \( T \). After replacing \( T \) by the members of a \( \tau \)-covering we may assume that \( b \) is the class of an element \( b \in U(T) \). After replacing \( T \) by the members of a \( \tau \)-covering we may assume that there exists an \( r' \in R'(T) \) such that \( a' = t(r') \) and \( s'(r') = f(b) \). Because the first diagram of the lemma is cartesian we can find \( r \in R(T) \) such that \( s(r) = b \) and \( f(r) = r' \). Then it is clear that \( a = t(r) \in U(T) \) is a section which maps to \((a', b)\).

\[
\square
\]

21. Descent in terms of groupoids

**Definition 21.1.** Let \( S \) be a scheme. Let \( f : (U', R', s', t', c') \rightarrow (U, R, s, t, c) \) be a morphism of groupoid schemes over \( S \). We say \( f \) is cartesian, or that \((U', R', s', t', c')\) is cartesian over \((U, R, s, t, c)\), if the diagram

\[
\begin{array}{ccc}
R' & \rightarrow & R \\
\downarrow f & & \downarrow s \\
U' & \rightarrow & U
\end{array}
\]

is a fibre square in the category of schemes. A *morphism of groupoid schemes cartesian over \((U, R, s, t, c)\)* is a morphism of groupoid schemes compatible with the structure morphisms towards \((U, R, s, t, c)\).

Cartesian morphisms are related to descent data. First we prove a general lemma describing the category of cartesian groupoid schemes over a fixed groupoid scheme.

**Lemma 21.2.** Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \). The category of groupoid schemes cartesian over \((U, R, s, t, c)\) is equivalent to the category of pairs \((V, \varphi)\) where \( V \) is a scheme over \( U \) and

\[
\varphi : V \times_{U,t} R \rightarrow R \times_{s,U} V
\]
is an isomorphism over $R$ such that $e^* \varphi = \text{id}_V$ and such that
$$c^* \varphi = \text{pr}_1^* \varphi \circ \text{pr}_0^* \varphi$$
as morphisms of schemes over $R \times_{s,U,t} R$.

**Proof.** The pullback notation in the lemma signifies base change. The displayed formula makes sense because
$$(R \times_{s,U,t} R) \times_{\text{pr}_1,R,\text{pr}_1} (V \times_{U,t} R) = (R \times_{s,U,t} R) \times_{\text{pr}_0,R,\text{pr}_0} (R \times_{s,U} V)$$
as schemes over $R \times_{s,U,t} R$.

Given $(V, \varphi)$ we set $U' = V$ and $R' = V \times_{U,t} R$. We set $t' : R' \to U'$ equal to the projection $V \times_{U,t} R \to V$. We set $s'$ equal to $\varphi$ followed by the projection $R \times_{s,U} V \to V$. We set $c' \to c$ equal to the composition
$$R' \times_{s',U',t'} R' \xrightarrow{\varphi,1} (R \times_{s,U} V) \times_V (V \times_{U,t} R) \to R \times_{s,U} V \times_{U,t} R$$
$$\xrightarrow{\varphi^{-1},1} V \times_{U,t} (R \times_{s,U,t} R) \to V \times_{U,t} R = R'$$

A computation, which we omit shows that we obtain a groupoid scheme over $(U, R, s, t, c)$. It is clear that this groupoid scheme is cartesian over $(U, R, s, t, c)$.

Conversely, given $f : (U', R', s', t', c') \to (U, R, s, t, c)$ cartesian then the morphisms
$$U' \times_{U,t} R \xleftarrow{t'} R' \xrightarrow{f,s'} R \times_{s,U} U'$$
are isomorphisms and we can set $V = U'$ and $\varphi$ equal to the composition $(f, s') \circ (t', f)^{-1}$. We omit the proof that $\varphi$ satisfies the conditions in the lemma. We omit the proof that these constructions are mutually inverse. □

Let $S$ be a scheme. Let $f : X \to Y$ be a morphism of schemes over $S$. Then we obtain a groupoid scheme $(X, X \times_Y X, \text{pr}_1, \text{pr}_0, c)$ over $S$. Namely, $j : X \times_Y X \to X \times_S X$ is an equivalence relation and we can take the associated groupoid, see Lemma 13.3.

**Lemma 21.3.** Let $S$ be a scheme. Let $f : X \to Y$ be a morphism of schemes over $S$. The construction of Lemma 21.2 determines an equivalence
category of groupoid schemes cartesian over $(X, X \times_Y X, \ldots)$ to category of descent data relative to $X/Y$

**Proof.** This is clear from Lemma 21.2 and the definition of descent data on schemes in Descent, Definition 31.1. □

22. Separation conditions

This really means conditions on the morphism $j : R \to U \times_S U$ when given a groupoid $(U, R, s, t, c)$ over $S$. As in the previous section we first formulate the corresponding diagram.
**Lemma 22.1.** Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid over $S$. Let $G \to U$ be the stabilizer group scheme. The commutative diagram

\[
\begin{array}{c}
R & \xrightarrow{f \mapsto (f, s(f))} & R \times_{s(U)} U \\
\downarrow & & \downarrow \\
R \times_{(U \times_S U)} R & \xrightarrow{(f, g) \mapsto (f, f^{-1} \circ g)} & R \times_{s(U)} G \\
\end{array}
\]

the two left horizontal arrows are isomorphisms and the right square is a fibre product square.

**Proof.** Omitted. Exercise in the definitions and the functorial point of view in algebraic geometry. □

**Lemma 22.2.** Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid over $S$. Let $G \to U$ be the stabilizer group scheme.

1. The following are equivalent
   a) $j : R \to U \times_S U$ is separated,
   b) $G \to U$ is separated, and
   c) $e : U \to G$ is a closed immersion.

2. The following are equivalent
   a) $j : R \to U \times_S U$ is quasi-separated,
   b) $G \to U$ is quasi-separated, and
   c) $e : U \to G$ is quasi-compact.

**Proof.** The group scheme $G \to U$ is the base change of $R \to U \times_S U$ by the diagonal morphism $U \to U \times_S U$, see Lemma 17.1. Hence if $j$ is separated (resp. quasi-separated), then $G \to U$ is separated (resp. quasi-separated). (See Schemes, Lemma 21.12). Thus (a) $\Rightarrow$ (b) in both (1) and (2).

If $G \to U$ is separated (resp. quasi-separated), then the morphism $U \to G$, as a section of the structure morphism $G \to U$ is a closed immersion (resp. quasi-compact), see Schemes, Lemma 21.11. Thus (b) $\Rightarrow$ (a) in both (1) and (2).

By the result of Lemma 22.1 (and Schemes, Lemmas 18.2 and 19.3) we see that if $e$ is a closed immersion (resp. quasi-compact) $\Delta_{R/U \times_S U}$ is a closed immersion (resp. quasi-compact). Thus (c) $\Rightarrow$ (a) in both (1) and (2). □

### 23. Finite flat groupoids, affine case

**Lemma 22.4.** Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine. In this case we get two ring maps $s^\sharp, t^\sharp : A \to B$. Let $C$ be the equalizer of $s^\sharp$ and $t^\sharp$. In a formula

\[
C = \{ a \in A \mid t^\sharp(a) = s^\sharp(a) \}.
\]

We will sometimes call this the ring of $R$-invariant functions on $U$. What properties does $M = \text{Spec}(C)$ have? The first observation is that the diagram

\[
\begin{array}{ccc}
R & \xrightarrow{s} & U \\
\downarrow & & \downarrow \\
U & \to & M
\end{array}
\]
is commutative, i.e., the morphism $U \to M$ equalizes $s,t$. Moreover, if $T$ is any affine scheme, and if $U \to T$ is a morphism which equalizes $s,t$, then $U \to T$ factors through $U \to M$. In other words, $U \to M$ is a coequalizer in the category of affine schemes.

We would like to find conditions that guarantee the morphism $U \to M$ is really a “quotient” in the category of schemes. We will discuss this at length elsewhere (insert future reference here); here we just discuss some special cases. Namely, we will focus on the case where $s,t$ are finite locally free.

**Example 23.1.** Let $k$ be a field. Let $U = \text{GL}_2,k$. Let $B \subset \text{GL}_2$ be the closed subgroup scheme of upper triangular matrices. Then the quotient sheaf $\text{GL}_2,k/B$ (in the Zariski, étale or fppf topology, see Definition 20.1) is representable by the projective line: $\mathbb{P}^1 = \text{GL}_2,k/B$. (Details omitted.) On the other hand, the ring of invariant functions in this case is just $k$. Note that in this case the morphisms $s,t : R = \text{GL}_2,k \times_k B \to \text{GL}_2,k = U$ are smooth of relative dimension 3.

Recall that in Exercises, Exercises 21.6 and 21.7 we have defined the determinant and the norm for finitely locally free modules and finite locally free ring extensions. If $\varphi : A \to B$ is a finite locally free ring map, then we will denote $\text{Norm}_\varphi(b) \in A$ the norm of $b \in B$. In the case of a finite locally free morphism of schemes, the norm was constructed in Divisors, Lemma 17.6.

**Lemma 23.2.** Let $S$ be a scheme. Let $(U,R,s,t,c)$ be a groupoid scheme over $S$. Assume $s,t : R = \text{GL}_2,k \times_k B \to \text{GL}_2,k = U$ are finite locally free. Let $C$ be as in (23.0.1). Let $f \in A$. Then $\text{Norm}_s(t^s(f)) \in C$.

**Proof.** Consider the commutative diagram

```
\[
\begin{array}{ccc}
U & \xrightarrow{t} & U \\
\downarrow & & \downarrow \\
R \times_{s,U,t} R & \xrightarrow{c} & R \\
\downarrow & & \downarrow \\
U & \xleftarrow{s} & R \\
\end{array}
\]
```

of Lemma 13.4. Think of $f \in \Gamma(U,\mathcal{O}_U)$. The commutativity of the top part of the diagram shows that $\text{pr}_0^*(t^s(f)) = c^t(t^s(f))$ as elements of $\Gamma(R \times_{s,U,t} R, \mathcal{O})$. Looking at the right lower cartesian square the compatibility of the norm construction with base change shows that $s^t(\text{Norm}_s(t^s(f))) = \text{Norm}_{\text{pr}_1^*}(c^t(t^s(f)))$. Similarly we get $t^s(\text{Norm}_s(t^s(f))) = \text{Norm}_{\text{pr}_0^*}(\text{pr}_0^*(t^s(f)))$. Hence by the first equality of this proof we see that $s^t(\text{Norm}_s(t^s(f))) = t^s(\text{Norm}_s(t^s(f)))$ as desired. □

**Lemma 23.3.** Let $S$ be a scheme. Let $(U,R,s,t,c)$ be a groupoid scheme over $S$. Assume $s,t : R \to U$ finite locally free. Then

$$U = \coprod_{r \geq 1} U_r$$

is a disjoint union of $R$-invariant opens such that the restriction $R_r$ of $R$ to $U_r$ has the property that $s,t : R_r \to U_r$ are finite locally free of rank $r$.  

Proof. By Morphisms, Lemma 46.5 there exists a decomposition $U = \bigsqcup_{r \geq 0} U_r$ such that $s : s^{-1}(U_r) \to U_r$ is finite locally free of rank $r$. As $s$ is surjective we see that $U_0 = \emptyset$. Note that $u \in U_r$ if and only if the scheme theoretic fibre $s^{-1}(u)$ has degree $r$ over $\kappa(u)$. Now, if $z \in R$ with $s(z) = u$ and $t(z) = u'$ then using notation as in Lemma 13.4

$$pr^{-1}_1(z) \to \Spec(\kappa(z))$$

is the base change of both $s^{-1}(u) \to \Spec(\kappa(u))$ and $s^{-1}(u') \to \Spec(\kappa(u'))$ by the lemma cited. Hence $u \in U_r$ if and only if the open subsets $U_r$ are $R$-invariant. In particular the restriction of $R$ to $U_r$ is just $s^{-1}(U_r)$ and $s : R_r \to U_r$ is finite locally free of rank $r$. As $t : R_r \to U_r$ is isomorphic to $s$ by the inverse of $R_r$ we see that it has also rank $r$. □

\begin{lemma}
Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume $U = \Spec(A)$ and $R = \Spec(B)$ are affine and $s, t : R \to U$ finite locally free of rank $r$. By Morphisms, Lemma 46.5 there exists a decomposition $U = \bigsqcup_{r \geq 0} U_r$ such that $s : s^{-1}(U_r) \to U_r$ is finite locally free of rank $r$. As $s$ is surjective we see that $U_0 = \emptyset$. Note that $u \in U_r$ if and only if the scheme theoretic fibre $s^{-1}(u)$ has degree $r$ over $\kappa(u)$. Now, if $z \in R$ with $s(z) = u$ and $t(z) = u'$ then using notation as in Lemma 13.4

$$pr^{-1}_1(z) \to \Spec(\kappa(z))$$

is the base change of both $s^{-1}(u) \to \Spec(\kappa(u))$ and $s^{-1}(u') \to \Spec(\kappa(u'))$ by the lemma cited. Hence $u \in U_r$ if and only if the open subsets $U_r$ are $R$-invariant. In particular the restriction of $R$ to $U_r$ is just $s^{-1}(U_r)$ and $s : R_r \to U_r$ is finite locally free of rank $r$. As $t : R_r \to U_r$ is isomorphic to $s$ by the inverse of $R_r$ we see that it has also rank $r$. □

Proof. First, by Lemma 23.3 we know that $(U, R, s, t, c)$ is a disjoint union of groupoid schemes $(U_r, R_r, s_r, t_r, c)$ such that each $s, t : R_r \to U_r$ has constant rank $r$. As $U$ is quasi-compact, we have $U_r = \emptyset$ for almost all $r$. It suffices to prove the lemma for each $(U_r, R_r, s_r, t_r, c)$ and hence we may assume that $s, t$ are finite locally free of rank $r$.

Assume that $s, t$ are finite locally free of rank $r$. Let $f \in A$. Consider the element $x - f \in A[x]$, where we think of $x$ as the coordinate on $A^1$. Since

$$(U \times A^1, R \times A^1, s \times \id_{A^1}, t \times \id_{A^1}, c \times \id_{A^1})$$

is also a groupoid scheme with finite source and target, we may apply Lemma 23.2 to it and we see that $P(x) = \Norm_{s,t}(t^2(x - f))$ is an element of $C[x]$. Because $s^2 : A \to B$ is finite locally free of rank $r$ we see that $P$ is monic of degree $r$. Moreover $P(f) = 0$ by Cayley-Hamilton (Algebra, Lemma 15.1). □

\begin{lemma}
Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume $U = \Spec(A)$ and $R = \Spec(B)$ are affine and $s, t : R \to U$ finite locally free of rank $r$. By Morphisms, Lemma 46.5 there exists a decomposition $U = \bigsqcup_{r \geq 0} U_r$ such that $s : s^{-1}(U_r) \to U_r$ is finite locally free of rank $r$. As $s$ is surjective we see that $U_0 = \emptyset$. Note that $u \in U_r$ if and only if the scheme theoretic fibre $s^{-1}(u)$ has degree $r$ over $\kappa(u)$. Now, if $z \in R$ with $s(z) = u$ and $t(z) = u'$ then using notation as in Lemma 13.4

$$pr^{-1}_1(z) \to \Spec(\kappa(z))$$

is the base change of both $s^{-1}(u) \to \Spec(\kappa(u))$ and $s^{-1}(u') \to \Spec(\kappa(u'))$ by the lemma cited. Hence $u \in U_r$ if and only if the open subsets $U_r$ are $R$-invariant. In particular the restriction of $R$ to $U_r$ is just $s^{-1}(U_r)$ and $s : R_r \to U_r$ is finite locally free of rank $r$. As $t : R_r \to U_r$ is isomorphic to $s$ by the inverse of $R_r$ we see that it has also rank $r$. □

Proof. First, by Lemma 23.3 we know that $(U, R, s, t, c)$ is a disjoint union of groupoid schemes $(U_r, R_r, s_r, t_r, c)$ such that each $s, t : R_r \to U_r$ has constant rank $r$. As $U$ is quasi-compact, we have $U_r = \emptyset$ for almost all $r$. It suffices to prove the lemma for each $(U_r, R_r, s_r, t_r, c)$ and hence we may assume that $s, t$ are finite locally free of rank $r$.

Assume that $s, t$ are finite locally free of rank $r$. Let $f \in A$. Consider the element $x - f \in A[x]$, where we think of $x$ as the coordinate on $A^1$. Since

$$(U \times A^1, R \times A^1, s \times \id_{A^1}, t \times \id_{A^1}, c \times \id_{A^1})$$

is also a groupoid scheme with finite source and target, we may apply Lemma 23.2 to it and we see that $P(x) = \Norm_{s,t}(t^2(x - f))$ is an element of $C[x]$. Because $s^2 : A \to B$ is finite locally free of rank $r$ we see that $P$ is monic of degree $r$. Moreover $P(f) = 0$ by Cayley-Hamilton (Algebra, Lemma 15.1). □

Proof. The proof of part (1) is omitted. Let us denote $A' = A \otimes_C C'$ and $B' = B \otimes_C C'$. Then we have

$$C^1 = \{ a \in A' | (t')^2(a) = (s')^2(a) \} = \{ a \in A \otimes_C C' | t^2 \otimes 1(a) = s^2 \otimes 1(a) \}.$$  

In other words, $C^1$ is the kernel of the difference map $(t^2 - s^2) \otimes 1$ which is just the base change of the $C$-linear map $t^2 - s^2 : A \to B$ by $C \to C'$. Hence (3) follows.
Proof of part (2)(b). Since \( C \to A \) is integral (Lemma 23.4) and injective we see that \( \text{Spec}(A) \to \text{Spec}(C) \) is surjective, see Algebra, Lemma 35.17. Thus also \( \text{Spec}(A') \to \text{Spec}(C') \) is surjective as a base change of a surjective morphism (Morphisms, Lemma 9.4). Hence \( \text{Spec}(C^1) \to \text{Spec}(C') \) is surjective also. This implies (2)(b) holds for example by Algebra, Lemma 29.6.

Proof of part (2)(a). By Lemma 23.3 our groupoid scheme \((U, R, s, t, c)\) decomposes as a finite disjoint union of groupoid schemes \((U_r, R_r, s, t, c)\) such that \( s, t : R_r \to U_r \) are finite locally free of rank \( r \). Pulling back by \( U' = \text{Spec}(C') \to U \) we obtain a similar decomposition of \( U' \) and \( U^1 = \text{Spec}(C^1) \). We will show in the next paragraph that (2)(a) holds for the corresponding system of rings \( A_r, B_r, C_r, C'_r, C^1_r \) with \( n = r \). Then given \( f \in C^1 \) let \( P_r \in C_r[x] \) be the polynomial whose image in \( C^1_r[x] \) is the image of \((x - f)^r \). Choosing a sufficiently divisible integer \( n \) we see that there is a polynomial \( P \in C'[x] \) whose image in \( C^1[x] \) is \((x - f)^n \); namely, we take \( P \) to be the unique element of \( C'[x] \) whose image in \( C'_r[x] \) is \( P_r^n/r \).

In this paragraph we prove (2)(a) in case the ring maps \( s^\sharp, t^\sharp : A \to B \) are finite locally free of a fixed rank \( r \). Let \( f \in C^1 \subset A' = A \otimes_C C' \). Choose a flat \( C \)-algebra \( D \) and a surjection \( D \to C' \). Choose a lift \( g \in A \otimes_C D \) of \( f \). Consider the polynomial

\[
P = \text{Norm}_{s^\sharp \otimes 1}(t^\sharp \otimes 1(x - g))
\]

in \((A \otimes_C D)[x]\). By Lemma 23.2 and part (3) of the current lemma the coefficients of \( P \) are in \( D \) (compare with the proof of Lemma 23.4). On the other hand, the image of \( P \) in \((A \otimes_C C')[x] \) is \((x - f)^r \) because \( t^\sharp \otimes 1(x - f) = s^\sharp(x - f) \) and \( s^\sharp \) is finite locally free of rank \( r \). This proves what we want with \( P \) as in the statement (2)(a) given by the image of our \( P \) under the map \( D[x] \to C'[x] \).

03BL \textbf{Lemma 23.6.} Let \( S \) be a scheme. Let \((U, R, s, t, c)\) be a groupoid scheme over \( S \). Assume \( U = \text{Spec}(A) \) and \( R = \text{Spec}(B) \) are affine and \( s, t : R \to U \) finite locally free. Let \( C \subset A \) be as in \((23.0.1)\). Then \( U \to M = \text{Spec}(C) \) has the following properties:

(1) the map on points \(|U| \to |M| \) is surjective and \( u_0, u_1 \in |U| \) map to the same point if and only if there exists a \( r \in |R| \) with \( t(r) = u_0 \) and \( s(r) = u_1 \), in a formula

\[
|M| = |U|/|R|
\]

(2) for any algebraically closed field \( k \) we have

\[
M(k) = U(k)/R(k)
\]

**Proof.** Let \( k \) be an algebraically closed field. Since \( C \to A \) is integral (Lemma 23.4) and injective we see that \( \text{Spec}(A) \to \text{Spec}(C) \) is surjective, see Algebra, Lemma 35.17. Thus \( |U| \to |M| \) is surjective. Let \( C \to k \) be a ring map. Since surjective morphisms are preserved under base change (Morphisms, Lemma 9.4) we see that \( A \otimes_C k \) is not zero. Now \( k \subset A \otimes_C k \) is a nonzero integral extension. Hence any residue field of \( A \otimes_C k \) is an algebraic extension of \( k \), hence equal to \( k \). Thus we see that \( U(k) \to M(k) \) is surjective.

Let \( a_0, a_1 : A \to k \) be ring maps. If there exists a ring map \( b : B \to k \) such that \( a_0 = b \circ t^\sharp \) and \( a_1 = b \circ s^\sharp \) then we see that \( a_0|_C = a_1|_C \) by definition. Conversely,
suppose that \( a_0|_C = a_1|_C \). Let us name this algebra map \( c : C \to k \). Consider the diagram

\[
\begin{array}{ccc}
B & \xleftarrow{a_1} & A \\
\downarrow{c} & & \downarrow{c} \\
C & \xleftarrow{a_0} & A
\end{array}
\]

We are trying to construct the dotted arrow, and if we do then part (2) follows, which in turn implies part (1). Since \( A \to B \) is finite and faithfully flat there exist finitely many ring maps \( b_1, \ldots, b_n : B \to k \) such that \( b_i \circ s^t = a_1 \). If the dotted arrow does not exist, then we see that none of the \( a'_i = b_i \circ t^t, \ i = 1, \ldots, n \) is equal to \( a_0 \). Hence the maximal ideals \( m'_i = \ker(a'_i \otimes 1 : A \otimes_C k \to k) \) of \( A \otimes_C k \) are distinct from \( m = \ker(a_0 \otimes 1 : A \otimes_C k \to k) \). By Algebra, Lemma \[14.2\] we would get an element \( f \in A \otimes_C k \) with \( f \in m \), but \( f \not\in m'_i \) for \( i = 1, \ldots, n \).

0DT9 \textbf{Lemma 23.7.} Let \( S \) be a scheme. Let \( f : (U', R', s', t') \to (U, R, s, t, c) \) be a morphism of groupoid schemes over \( S \).

(1) \( U, R, U', R' \) are affine,
(2) \( s, t, s', t' \) are finite locally free,
(3) the diagrams

\[
\begin{array}{ccc}
R' & \xrightarrow{f} & R \\
\downarrow{s'} & & \downarrow{s} \\
U' & \xleftarrow{f} & U \\
G' & \xrightarrow{f} & G \\
\downarrow{t'} & & \downarrow{t} \\
U' & \xleftarrow{f} & U
\end{array}
\]

are cartesian where \( G \) and \( G' \) are the stabilizer group schemes, and

(4) \( f : U' \to U \) is étale.

Then the map \( C \to C' \) from the \( R \)-invariant functions on \( U \) to the \( R' \)-invariant functions on \( U' \) is étale and \( U' = \text{Spec}(C') \times_{\text{Spec}(C)} U \).
Proof. Set $M = \text{Spec}(C)$ and $M' = \text{Spec}(C')$. Write $U = \text{Spec}(A)$, $U' = \text{Spec}(A')$, $R = \text{Spec}(B)$, and $R' = \text{Spec}(B')$. We will use the results of Lemmas 23.4, 23.5, and 23.6 without further mention.

Assume $C$ is a strictly henselian local ring. Let $p \in M$ be the closed point and let $p' \in M'$ map to $p$. Claim: in this case there is a disjoint union decomposition $(U', R', s', t', c') = (U, R, s, t, c) \amalg (U''', R''', s'', t'', c'')$ over $(U, R, s, t, c)$ such that for the corresponding disjoint union decomposition $M' = M \amalg M''$ over $M$ the point $p'$ corresponds to $p \in M$.

The claim implies the lemma. Suppose that $M_1 \to M$ is a flat morphism of affine schemes. Then we can base change everything to $M_1$ without affecting the hypotheses (1) – (4). From Lemma 23.5 we see $M_1$, resp. $M_1'$ is the spectrum of the $R_1$-invariant functions on $U_1$, resp. the $R_1'$-invariant functions on $U_1'$. Suppose that $p' \in M'$ maps to $p \in M$. Let $M_1$ be the spectrum of the strict henselization of $O_{M,p}$ with closed point $p_1 \in M_1$. Choose a point $p_1' \in M_1'$ mapping to $p_1$ and $p'$. From the claim we get

$$(U_1', R_1', s_1', t_1', c_1') = (U_1, R_1, s_1, t_1, c_1) \amalg (U_1'', R_1'', s_1'', t_1'', c_1'')$$

and correspondingly $M_1 = M_1 \amalg M_1''$ as a scheme over $M_1$. Write $M_1 = \text{Spec}(C_1)$ and write $C_1 = \text{colim}_i C_i$ as a filtered colimit of étale $C$-algebras. Set $M_i = \text{Spec}(C_i)$. The $M_1 = \lim_i M_i$ and similarly for the other schemes. By Limits, Lemmas 8.11 and 11.11 we can find an $i$ such that

$$(U_1', R_1', s_i', t_i', c_i') = (U_1, R_1, s_i, t_i, c_i) \amalg (U_1'', R_1'', s_i'', t_i'', c_i'')$$

We conclude that $M_i = M_1 \amalg M_i''$. In particular $M' \to M$ becomes étale at a point over $p'$ after an étale base change. This implies that $M' \to M$ is étale at $p'$ (for example by Morphisms, Lemma 34.17). We will prove $U' \cong M' \times_M U$ after we prove the claim.

Proof of the claim. Observe that $U_p$ and $U_p'$ have finitely many points. For $u \in U_p$ we have $k(u)/k(p)$ is algebraic, hence $k(u)$ is separably closed. As $U' \to U$ is étale, we conclude the morphism $U_p' \to U_p$ induces isomorphisms on residue field extensions. Let $u' \in U_p'$ with image $u \in U_p$. By assumption (3) the morphism of scheme theoretic fibres $(s')^{-1}(u') \to s^{-1}(u)$, $(t')^{-1}(u') \to t^{-1}(u)$, and $G_{u'} \to G_u$ are isomorphisms. Observing that $U_p = t(s^{-1}(u))$ (set theoretically) we conclude that the points of $U_p'$ surject onto the points of $U_p$. Suppose that $u_1'$ and $u_2'$ are points of $U_p'$ mapping to the same point $u$ of $U_p$. Then there exists a point $r' \in R_{u'}'$ with $s'(r') = u_1'$ and $t'(r') = u_2'$. Consider the two towers of fields

$$k(r')/k(u_1') \to k(u)/k(p)$$

$$k(r')/k(u_2') \to k(p)$$

whose “ends” are the same as the two “ends” of the two towers

$$k(r')/k(u_1') \to k(p') \to k(p)$$

$$k(r')/k(u_2') \to k(p') \to k(p)$$

These two induce the same maps $k(p') \to k(r')$ as $(U_p', R_{u'}', s', t', c')$ is a groupoid over $p'$. Since $k(u)/k(p)$ is purely inseparable, we conclude that the two induced maps $k(u) \to k(r')$ are the same. Therefore $r'$ maps to a point of the fibre $G_u$. By assumption (3) we conclude that $r' \in (G')_{u_1'}$. Namely, we may think of $G$ as a closed subscheme of $R$ viewed as a scheme over $U$ via $s$ and use that the base change to $U'$ gives $G' \subset R'$. In particular we have $u_1' = u_2'$. We conclude that $U_p' \to U_p$ is a bijective map on points inducing isomorphisms on residue fields. It
follows that $U'_p$ is a finite set of closed points (Algebra, Lemma 34.9) and hence $U'_p$ is closed in $U'$. Let $J' \subset A'$ be the radical ideal cutting out $U'_p$ set theoretically.

Second part proof of the claim. Let $m \subset C$ be the maximal ideal. Observe that $(A, mA)$ is a henselian pair by More on Algebra, Lemma 11.8. Let $J = \sqrt{mA}$. Then $(A, J)$ is a henselian pair (More on Algebra, Lemma 11.7) and the étale ring map $A \to A'$ induces an isomorphism $A/J \to A'/J'$ by our deliberations above. We conclude that $A' = A \times A''$ by More on Algebra, Lemma 11.6. Consider the corresponding disjoint union decomposition $U' = U \amalg U''$. The open $(s')^{-1}(U)$ is the set of points of $R'$ specializing to a point of $R'_p$. Similarly for $(t')^{-1}(U)$. Similarly we have $(s')^{-1}(U'' = (t')^{-1}(U'')$ as this is the set of points which do not specialize to $R'_p$. Hence we obtain a disjoint union decomposition

$$(U', R', s', t', c') = (U, R, s, t, c) \amalg (U'', R'', s'', t'', c'')$$

This immediately gives $M' = M \amalg M''$ and the proof of the claim is complete.

We still have to prove that the canonical map $U' \to M' \times_M U$ is an isomorphism. It is an étale morphism (Morphisms, Lemma 34.18). On the other hand, by base changing to strictly henselian local rings (as in the third paragraph of the proof) and using the bijectivity $U'_p \to U_p$ established in the course of the proof of the claim, we see that $U' \to M' \times_M U$ is universally bijective (some details omitted). However, a universally bijective étale morphism is an isomorphism (Descent, Lemma 22.2) and the proof is complete.

**Lemma 23.8.** Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$.

Assume

1. $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine, and
2. there exist elements $x_i \in A$, $i \in I$ such that $B = \bigoplus_{i \in I} s^i(A)t^i(x_i)$.

Then $A = \bigoplus_{i \in I} Cx_i$, and $B \cong A \otimes_C A$ where $C \subset A$ is the $R$-invariant functions on $U$ as in \[23.6.1\].

**Proof.** During this proof we will write $s, t : A \to B$ instead of $s^i, t^i$, and similarly $c : B \to B \otimes_{s, A, t} B$. We write $p_0 : B \to B \otimes_{s, A, t} B$, $b \mapsto b \otimes 1$ and $p_1 : B \to B \otimes_{s, A, t} B$, $b \mapsto 1 \otimes b$. By Lemma 13.3 and the definition of $C$ we have the following commutative diagram

$$
\begin{array}{ccc}
B \otimes_{s, A, t} B & \xrightarrow{c} & B \\
\downarrow{p_0} & & \downarrow{s} \\
B & \xleftarrow{t} & A \\
\end{array}
$$

Moreover the tow left squares are cocartesian in the category of rings, and the top row is isomorphic to the diagram

$$
\begin{array}{ccc}
B \otimes_{t, A, t} B & \xrightarrow{p_1} & B \\
\downarrow{p_0} & & \downarrow{t} \\
B & \xleftarrow{t} & A \\
\end{array}
$$

which is an equalizer diagram according to Descent, Lemma 3.6 because condition (2) implies in particular that $s$ (and hence also then isomorphic arrow $t$) is faithfully
flat. The lower row is an equalizer diagram by definition of $C$. We can use the $x_i$ and get a commutative diagram

\[
\begin{array}{c}
B \otimes_{s,A,t} B \xrightarrow{c} B \xleftarrow{t} A \\
p_1 \downarrow \quad \downarrow s \quad s_0 \downarrow \quad \downarrow t \\
\bigoplus_{i \in I} Bx_i \xleftarrow{s} \bigoplus_{i \in I} Ax_i \xleftarrow{t} \bigoplus_{i \in I} Cx_i
\end{array}
\]

where in the right vertical arrow we map $x_i$ to $x_i$, in the middle vertical arrow we map $x_i$ to $t(x_i)$, and in the left vertical arrow we map $x_i$ to $c(t(x_i)) = t(x_i) \otimes 1 = p_0(t(x_i))$ (equality by the commutativity of the top part of the diagram in Lemma 13.4). Then the diagram commutes. Moreover the middle vertical arrow is an isomorphism by assumption. Since the left two squares are cocartesian we conclude that also the left vertical arrow is an isomorphism. On the other hand, the horizontal rows are exact (i.e., they are equalizers). Hence we conclude that also the right vertical arrow is an isomorphism. □

**Proposition 23.9.** Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume

1. $U = \text{Spec}(A)$, and $R = \text{Spec}(B)$ are affine,
2. $s, t : R \to U$ finite locally free, and
3. $j = (t, s)$ is an equivalence.

In this case, let $C \subset A$ be as in (23.0.1). Then $U \to M = \text{Spec}(C)$ is finite locally free and $R = U \times_M U$. Moreover, $M$ represents the quotient sheaf $U/R$ in the fppf topology (see Definition 20.1).

**Proof.** During this proof we use the notation $s, t : A \to B$ instead of the notation $s^\sharp, t^\sharp$. By Lemma 20.3 it suffices to show that $C \to A$ is finite locally free and that the map

\[ t \otimes s : A \otimes_C A \to B \]

is an isomorphism. First, note that $j$ is a monomorphism, and also finite (since already $s$ and $t$ are finite). Hence we see that $j$ is a closed immersion by Morphisms, Lemma 42.15. Hence $A \otimes_C A \to B$ is surjective.

We will perform base change by flat ring maps $C \to C'$ as in Lemma 23.5 and we will use that formation of invariants commutes with flat base change; see part (3) of the lemma cited. We will show below that for every prime $p \subset C$, there exists a local flat ring map $C_p \to C'_p$ such that the result holds after a base change to $C'_p$. This implies immediately that $A \otimes_C A \to B$ is injective (use Algebra, Lemma 22.1). It also implies that $C \to A$ is flat, by combining Algebra, Lemmas 38.17, 38.19, and 38.8. Then since $U \to \text{Spec}(C)$ is surjective also (Lemma 23.6) we conclude that $C \to A$ is faithfully flat. Then the isomorphism $B \cong A \otimes_C A$ implies that $A$ is a finitely presented $C$-module, see Algebra, Lemma 82.2. Hence $A$ is finite locally free over $C$, see Algebra, Lemma 77.2.

By Lemma 23.3 we know that $A$ is a finite product of rings $A_r$ and $B$ is a finite product of rings $B_r$ such that the groupoid scheme decomposes accordingly (see the proof of Lemma 23.4). Then also $C$ is a product of rings $C_r$ and correspondingly $C'$ decomposes as a product. Hence we may and do assume that the ring maps $s, t : A \to B$ are finite locally free of a fixed rank $r$. 

03BM
The local ring maps $C_p \to C'_p$ we are going to use are any local flat ring maps such that the residue field of $C'_p$ is infinite. By Algebra, Lemma 23.6 such local ring maps exist.

Assume $C$ is a local ring with maximal ideal $\mathfrak{m}$ and infinite residue field, and assume that $s, t : A \to B$ is finite locally free of constant rank $r > 0$. Since $C \subset A$ is integral (Lemma 23.4) all primes lying over $\mathfrak{m}$ are maximal, and all maximal ideals of $A$ lie over $\mathfrak{m}$. Similarly for $C \subset B$. Pick a maximal ideal $\mathfrak{m}'$ of $A$ lying over $\mathfrak{m}$ (exists by Lemma 23.6). Since $t : A \to B$ is finite locally free there exist at most finitely many maximal ideals of $B$ lying over $\mathfrak{m}'$. Hence we conclude (by Lemma 23.6 again) that $A$ has finitely many maximal ideals, i.e., $A$ is semi-local. This in turn implies that $B$ is semi-local as well. OK, and now, because $t \otimes s : A \otimes C A \to B$ is surjective, we can apply Algebra, Lemma 77.7 to the ring map $C \to A$, the $A$-module $M = B$ (seen as an $A$-module via $t$) and the $C$-submodule $s(A) \subset B$. This lemma implies that there exist $x_1, \ldots, x_r \in A$ such that $M$ is free over $A$ on the basis $s(x_1), \ldots, s(x_r)$. Hence we conclude that $C \to A$ is finite free and $B \cong A \otimes C A$ by applying Lemma 23.8.

24. Finite flat groupoids

In this section we prove a lemma that will help to show that the quotient of a scheme by a finite flat equivalence relation is a scheme, provided that each equivalence class is contained in an affine. See Properties of Spaces, Proposition 14.1.

Lemma 24.1. Let $S$ be a scheme. Let $(U, R, s, t, c)$ be a groupoid scheme over $S$. Assume $s, t$ are finite locally free. Let $u \in U$ be a point such that $t(s^{-1}\{u\})$ is contained in an affine open of $U$. Then there exists an $R$-invariant affine open neighbourhood of $u$ in $U$.

Proof. Since $s$ is finite locally free it has finite fibres. Hence $t(s^{-1}\{u\}) = \{u_1, \ldots, u_n\}$ is a finite set. Note that $u \in \{u_1, \ldots, u_n\}$. Let $W \subset U$ be an affine open containing $\{u_1, \ldots, u_n\}$, in particular $u \in W$. Consider $Z = R \setminus s^{-1}(W) \cap t^{-1}(W)$. This is a closed subset of $R$. The image $t(Z)$ is a closed subset of $U$ which can be loosely described as the set of points of $U$ which are $R$-equivalent to a point of $U \setminus W$. Hence $W' = U \setminus t(Z)$ is an $R$-invariant, open subscheme of $U$ contained in $W$, and $\{u_1, \ldots, u_n\} \subset W'$. Picture

$$\{u_1, \ldots, u_n\} \subset W' \subset W \subset U.$$ 

Let $f \in \Gamma(W, \mathcal{O}_W)$ be an element such that $\{u_1, \ldots, u_n\} \subset D(f) \subset W'$. Such an $f$ exists by Algebra, Lemma 14.2. By our choice of $W'$ we have $s^{-1}(W') \subset t^{-1}(W)$, and hence we get a diagram

$$s^{-1}(W') \xrightarrow{t} W$$

The vertical arrow is finite locally free by assumption. Set

$$g = \text{Norm}_x(t^*f) \in \Gamma(W', \mathcal{O}_{W'})$$

By construction $g$ is a function on $W'$ which is nonzero in $u$, as $t^*(f)$ is nonzero in each of the points of $R$ lying over $u$, since $f$ is nonzero in $u_1, \ldots, u_n$. Similarly,
$D(g) \subset W'$ is equal to the set of points $w$ such that $f$ is not zero in any of the points equivalent to $w$. This means that $D(g)$ is an $R$-invariant affine open of $W'$. The final picture is 

$$\{u_1, \ldots, u_n\} \subset D(g) \subset D(f) \subset W' \subset W \subset U$$

and hence we win. □

25. Descending quasi-projective schemes

We can use Lemma [24.1] to show that a certain type of descent datum is effective.

**Lemma 25.1.** Let $X \to Y$ be a surjective finite locally free morphism. Let $V$ be a scheme over $X$ such that for all $(y, v_1, \ldots, v_d)$ where $y \in Y$ and $v_1, \ldots, v_d \in V_y$ there exists an affine open $U \subset V$ with $v_1, \ldots, v_d \in U$. Then any descent datum on $V/X/Y$ is effective.

**Proof.** Let $\varphi$ be a descent datum as in Descent, Definition [31.1]. Recall that the functor from schemes over $Y$ to descent data relative to $\{X \to Y\}$ is fully faithful, see Descent, Lemma [32.11]. Thus using Constructions, Lemma [2.1] it suffices to prove the lemma in the case that $Y$ is affine. Some details omitted (this argument can be avoided if $Y$ is separated or has affine diagonal, because then every morphism from an affine scheme to $X$ is affine).

Assume $Y$ is affine. If $V$ is also affine, then we have effectivity by Descent, Lemma [34.1]. Hence by Descent, Lemma [32.13] it suffices to prove that every point $v$ of $V$ has a $\varphi$-invariant affine open neighbourhood. Consider the groupoid $(X, X \times Y X, pr_1, pr_0, pr_{02})$. By Lemma [21.3] the descent datum $\varphi$ determines and is determined by a cartesian morphism of groupoid schemes 

$$(V, R, s, t, c) \to (X, X \times Y X, pr_1, pr_0, pr_{02})$$

over Spec($\mathbb{Z}$). Since $X \to Y$ is finite locally free, we see that $pr_i : X \times Y X \to X$ and hence $s$ and $t$ are finite locally free. In particular the $R$-orbit $t(s^{-1}(\{v\}))$ of our point $v \in V$ is finite. Using the equivalence of categories of Lemma [21.3] once more we see that $\varphi$-invariant opens of $V$ are the same thing as $R$-invariant opens of $V$. Our assumption shows there exists an affine open of $V$ containing the orbit $t(s^{-1}(\{v\}))$ as all the points in this orbit map to the same point of $Y$. Thus Lemma [24.1] provides an $R$-invariant affine open containing $v$. □

**Lemma 25.2.** Let $X \to Y$ be a surjective finite locally free morphism. Let $V$ be a scheme over $X$ such that one of the following holds

1. $V \to X$ is projective,
2. $V \to X$ is quasi-projective,
3. there exists an ample invertible sheaf on $V$,
4. there exists an $X$-ample invertible sheaf on $V$,
5. there exists an $X$-very ample invertible sheaf on $V$.

Then any descent datum on $V/X/Y$ is effective.

**Proof.** We check the condition in Lemma [25.1]. Let $y \in Y$ and $v_1, \ldots, v_d \in V$ points over $y$. Case (1) is a special case of (2), see Morphisms, Lemma [41.10]. Case (2) is a special case of (4), see Morphisms, Definition [38.1]. If there exists an ample invertible sheaf on $V$, then there exists an affine open containing $v_1, \ldots, v_d$ by Properties, Lemma [29.5]. Thus (3) is true. In cases (4) and (5) it is harmless to
replace $Y$ by an affine open neighbourhood of $y$. Then $X$ is affine too. In case (4) we see that $V$ has an ample invertible sheaf by Morphisms, Definition 35.1 and the result follows from case (3). In case (5) we can replace $V$ by a quasi-compact open containing $v_1, \ldots, v_d$ and we reduce to case (4) by Morphisms, Lemma 36.2. □
