1. Introduction

In this chapter we construct the intersection product on the Chow groups modulo rational equivalence on a nonsingular projective variety over an algebraically closed field. Our tools are Serre’s Tor formula (see [Ser65 Chapter V]), reduction to the diagonal, and the moving lemma.

This is a chapter of the Stacks Project, version 4decab0f, compiled on Oct 15, 2018.
We first recall cycles and how to construct proper pushforward and flat pullback of cycles. Next, we introduce rational equivalence of cycles which gives us the Chow groups $A_*(X)$. Proper pushforward and flat pullback factor through rational equivalence to give operations on Chow groups. This takes up Sections 3, 4, 5, 6, 7, 8, 9, 10, and 11. For proofs we mostly refer to the chapter on Chow homology where these results have been proven in the setting of schemes locally of finite type over a universally catenary Noetherian base, see Chow Homology, Section 7 ff.

Since we work on a nonsingular projective $X$ any irreducible component of the intersection $V \cap W$ of two irreducible closed subvarieties has dimension at least $\dim(V) + \dim(W) - \dim(X)$. We say $V$ and $W$ intersect properly if equality holds for every irreducible component $Z$. In this case we define the intersection multiplicity $e_Z = e(X, V \cdot W, Z)$ by the formula

$$ e_Z = \sum_i (-1)^i \text{length}_{O_{X,Z}} \text{Tor}_i^{O_{X,Z}}(O_{W,Z}, O_{V,Z}) $$

We need to do a little bit of commutative algebra to show that these intersection multiplicities agree with intuition in simple cases, namely, that sometimes $e_Z = \text{length}_{O_{X,Z}} O_{V \cap W, Z}$, in other words, only $\text{Tor}_0$ contributes. This happens when $V$ and $W$ are Cohen-Macaulay in the generic point of $Z$ or when $W$ is cut out by a regular sequence in $O_{X,Z}$ which also defines a regular sequence on $O_{V,Z}$. However, Example 14.4 shows that higher tors are necessary in general. Moreover, there is a relationship with the Samuel multiplicity. These matters are discussed in Sections 13, 14, 15, 16, and 17.

Reduction to the diagonal is the statement that we can intersect $V$ and $W$ by intersecting $V \times W$ with the diagonal in $X \times X$. This innocuous statement, which is clear on the level of scheme theoretic intersections, reduces an intersection of a general pair of closed subschemes, to the case where one of the two is locally cut out by a regular sequence. We use this, following Serre, to obtain positivity of intersection multiplicities. Moreover, reduction to the diagonal leads to additivity of intersection multiplicities, associativity, and a projection formula. This can be found in Sections 18, 19, 20, 21, and 22.

Finally, we come to the moving lemmas and applications. There are two parts to the moving lemma. The first is that given closed subvarieties

$$ Z \subset X \subset \mathbb{P}^N $$

with $X$ nonsingular, we can find a subvariety $C \subset \mathbb{P}^N$ intersecting $X$ properly such that

$$ C \cdot X = [Z] + \sum m_j[Z_j] $$

and such that the other components $Z_j$ are “more general” than $Z$. The second part is that one can move $C \subset \mathbb{P}^N$ over a rational curve to a subvariety in general position with respect to any given list of subvarieties. Combined these results imply that it suffices to define the intersection product of cycles on $X$ which intersect properly which was done above. Of course this only leads to an intersection product on $A_*(X)$ if one can show, as we do in the text, that these products pass through rational equivalence. This and some applications are discussed in Sections 23, 24, 25, 26, 27, and 28.
2. Conventions

0AZ8 We fix an algebraically closed ground field $\mathbb{C}$ of any characteristic. All schemes and varieties are over $\mathbb{C}$ and all morphisms are over $\mathbb{C}$. A variety $X$ is nonsingular if $X$ is a regular scheme (see Properties, Definition 9.1). In our case this means that the morphism $X \to \text{Spec}(\mathbb{C})$ is smooth (see Varieties, Lemma 12.6).

3. Cycles

0AZ9 Let $X$ be a variety. A closed subvariety of $X$ is an integral closed subscheme $Z \subset X$. A $k$-cycle on $X$ is a finite formal sum $\sum n_i [Z_i]$ where each $Z_i$ is a closed subvariety of dimension $k$. Whenever we use the notation $\alpha = \sum n_i [Z_i]$ for a $k$-cycle we always assume the subvarieties $Z_i$ are pairwise distinct and $n_i \neq 0$ for all $i$. In this case the support of $\alpha$ is the closed subset

$$\text{Supp}(\alpha) = \bigcup Z_i \subset X$$

of dimension $k$. The group of $k$-cycles is denoted $Z_k(X)$. See Chow Homology, Section 8.

4. Cycle associated to closed subscheme

0AZA Suppose that $X$ is a variety and that $Z \subset X$ be a closed subscheme with $\dim(Z) \leq k$. Let $Z_i$ be the irreducible components of $Z$ of dimension $k$ and let $n_i$ be the multiplicity of $Z_i$ in $Z$ defined as

$$n_i = \text{length}_{\mathcal{O}_{X,Z_i}} \mathcal{O}_{Z,Z_i}$$

where $\mathcal{O}_{X,Z}$, resp. $\mathcal{O}_{Z,Z_i}$ is the local ring of $X$, resp. $Z$ at the generic point of $Z_i$. We define the $k$-cycle associated to $Z$ to be the $k$-cycle

$$[Z]_k = \sum n_i [Z_i].$$

See Chow Homology, Section 9.

5. Cycle associated to a coherent sheaf

0AZB Suppose that $X$ is a variety and that $\mathcal{F}$ is a coherent $\mathcal{O}_X$-module with $\dim(\text{Supp}(\mathcal{F})) \leq k$. Let $Z_i$ be the irreducible components of $\text{Supp}(\mathcal{F})$ of dimension $k$ and let $n_i$ be the multiplicity of $Z_i$ in $\mathcal{F}$ defined as

$$n_i = \text{length}_{\mathcal{O}_{X,Z_i}} \mathcal{F}_{\xi_i}$$

where $\mathcal{O}_{X,Z_i}$ is the local ring of $X$ at the generic point $\xi_i$ of $Z_i$ and $\mathcal{F}_{\xi_i}$ is the stalk of $\mathcal{F}$ at this point. We define the $k$-cycle associated to $\mathcal{F}$ to be the $k$-cycle

$$[\mathcal{F}]_k = \sum n_i [Z_i].$$

See Chow Homology, Section 10. Note that, if $Z \subset X$ is a closed subscheme with $\dim(Z) \leq k$, then $[Z]_k = [\mathcal{O}_Z]_k$ by definition.
6. Proper pushforward

Suppose that $f : X \to Y$ is a proper morphism of varieties. Let $Z \subset X$ be a $k$-dimensional closed subvariety. We define $f_*[Z]$ to be $0$ if $\dim(f(Z)) < k$ and $d \cdot [f(Z)]$ if $\dim(f(Z)) = k$ where

$$d = \lceil C(Z) : C(f(Z)) \rceil = \deg(Z/f(Z))$$

is the degree of the dominant morphism $Z \to f(Z)$, see Morphisms, Definition [49.8]. Let $\alpha = \sum n_i[Z_i]$ be a $k$-cycle on $Y$. The pushforward of $\alpha$ is the sum $f_*\alpha = \sum n_i f_*[Z_i]$ where each $f_*[Z_i]$ is defined as above. This defines a homomorphism

$$f_* : Z_k(X) \to Z_k(Y)$$

See Chow Homology, Section [12].  

Lemma 6.1. Suppose that $f : X \to Y$ is a proper morphism of varieties. Let $\mathcal{F}$ be a coherent sheaf with $\dim(\text{Supp}(\mathcal{F})) \leq k$, then $f_*[\mathcal{F}]_k = [f_*\mathcal{F}]_k$. In particular, if $Z \subset X$ is a closed subscheme of dimension $\leq k$, then $f_*[Z] = [f_*\mathcal{O}_Z]_k$.

Proof. See Chow Homology, Lemma [12.3].

Lemma 6.2. Let $f : X \to Y$ and $g : Y \to Z$ be proper morphisms of varieties. Then $g_* \circ f_* = (g \circ f)_*$ as maps $Z_k(X) \to Z_k(Z)$.

Proof. Special case of Chow Homology, Lemma [12.2].

7. Flat pullback

Suppose that $f : X \to Y$ is a flat morphism of varieties. By Morphisms, Lemma [27.2] every fibre of $f$ has dimension $r = \dim(X) - \dim(Y)$ [1]. Let $Z \subset X$ be a $k$-dimensional closed subvariety. We define $f^*[Z]$ to be the $(k + r)$-cycle associated to the scheme theoretic inverse image: $f^*[Z] = [f^{-1}(Z)]_{k+r}$. Let $\alpha = \sum n_i[Z_i]$ be a $k$-cycle on $Y$. The pullback of $\alpha$ is the sum $f_*\alpha = \sum n_i f^*[Z_i]$ where each $f^*[Z_i]$ is defined as above. This defines a homomorphism

$$f^* : Z_k(Y) \to Z_{k+r}(X)$$

See Chow Homology, Section [14].

Lemma 7.1. Let $f : X \to Y$ be a flat morphism of varieties. Set $r = \dim(X) - \dim(Y)$. Then $f^*[\mathcal{F}]_k = [f^*\mathcal{F}]_{k+r}$ if $\mathcal{F}$ is a coherent sheaf on $Y$ and the dimension of the support of $\mathcal{F}$ is at most $k$.

Proof. See Chow Homology, Lemma [14.4].

Lemma 7.2. Let $f : X \to Y$ and $g : Y \to Z$ be flat morphisms of varieties. Then $g \circ f$ is flat and $f^* \circ g^* = (g \circ f)^*$ as maps $Z_k(Z) \to Z_{k+\dim(X)-\dim(Z)}(X)$.

Proof. Special case of Chow Homology, Lemma [14.3].
8. Rational Equivalence

We are going to define rational equivalence in a way which at first glance may seem different from what you are used to, or from what is in [Ful98, Chapter I] or Chow Homology, Section 19. However, in Section 9 we will show that the two notions agree.

Let $X$ be a variety. Let $W \subset X \times \mathbb{P}^1$ be a closed subvariety of dimension $k + 1$. Let $a, b$ be distinct closed points of $\mathbb{P}^1$. Assume that $X \times a, X \times b$ and $W$ intersect properly:

$$\dim(W \cap X \times a) \leq k, \quad \dim(W \cap X \times b) \leq k.$$ 

This is true as soon as $W \to \mathbb{P}^1$ is dominant or if $W$ is contained in a fibre of the projection over a closed point different from $a$ or $b$ (this is an uninteresting case which we will discard). In this situation the scheme theoretic fibre $W_a$ of the morphism $W \to \mathbb{P}^1$ is equal to the scheme theoretic intersection $W \cap X \times a$ in $X \times \mathbb{P}^1$. Identifying $X \times a$ and $X \times b$ with $X$ we may think of the fibres $W_a$ and $W_b$ as closed subschemes of $X$ of dimension $\leq k^2$. A basic example of a rational equivalence is

$$[W_a]_k \sim_{\text{rat}} [W_b]_k$$

The cycles $[W_a]_k$ and $[W_b]_k$ are easy to compute in practice (given $W$) because they are obtained by proper intersection with a Cartier divisor (we will see this in Section 17). Since the automorphism group of $\mathbb{P}^1$ is 2-transitive we may move the pair of closed points $a, b$ to any pair we like. A traditional choice is to choose $a = 0$ and $b = \infty$.

More generally, let $\alpha = \sum n_i [W_i]$ be a $(k + 1)$-cycle on $X \times \mathbb{P}^1$. Let $a_i, b_i$ be pairs of distinct closed points of $\mathbb{P}^1$. Assume that $X \times a_i, X \times b_i$ and $W_i$ intersect properly, in other words, each $W_i, a_i, b_i$ satisfies the condition discussed above. A cycle rationally equivalent to zero is any cycle of the form

$$\sum n_i ([W_i, a_i]_k - [W_i, b_i]_k).$$

This is indeed a $k$-cycle. The collection of $k$-cycles rationally equivalent to zero is an additive subgroup of the group of $k$-cycles. We say two $k$-cycles are rationally equivalent, notation $\alpha \sim_{\text{rat}} \alpha'$, if $\alpha - \alpha'$ is a cycle rationally equivalent to zero.

We define

$$A_k(X) = Z_k(X)/\sim_{\text{rat}}$$

to be the Chow group of $k$-cycles on $X$. We will see in Lemma [9.1] that this agrees with the Chow group as defined in Chow Homology, Definition [19.1].

9. Rational equivalence and rational functions

Let $X$ be a variety. Let $W \subset X$ be a subvariety of dimension $k + 1$. Let $f \in C(W)^*$ be a nonzero rational function on $W$. For every subvariety $Z \subset W$ of dimension $k$ one can define the order of vanishing $\text{ord}_{W, Z}(f)$ of $f$ at $Z$. If $f$ is an element of the local ring $O_{W, Z}$, then one has

$$\text{ord}_{W, Z}(f) = \text{length}_{O_{X, Z}} O_{W, Z}/f O_{W, Z}$$

We will sometimes think of $W_a$ as a closed subscheme of $X \times \mathbb{P}^1$ and sometimes as a closed subscheme of $X$. It should always be clear from context which point of view is taken.
where $\mathcal{O}_{X,Z}$, resp. $\mathcal{O}_{W,Z}$ is the local ring of $X$, resp. $W$ at the generic point of $Z$. In general one extends the definition by multiplicativity. The principal divisor associated to $f$ is

$$\text{div}_W(f) = \sum \text{ord}_{W,Z}(f)[Z]$$

in $Z_k(W)$. Since $W \subset X$ is a closed subvariety we may think of $\text{div}_W(f)$ as a cycle on $X$. See Chow Homology, Section 17.

**Lemma 9.1.** Let $X$ be a variety. Let $W \subset X$ be a subvariety of dimension $k + 1$. Let $f \in C(W)^*$ be a nonzero rational function on $W$. Then $\text{div}_W(f)$ is rationally equivalent to zero on $X$. Conversely, these principal divisors generate the abelian group of cycles rationally equivalent to zero on $X$.

**Proof.** The first assertion follows from Chow Homology, Lemma 18.2. More precisely, let $W' \subset X \times \mathbf{P}^1$ be the closure of the graph of $f$. Then $\text{div}_W(f) = [W'_0]_k - [W'_\infty]_k$ in $Z_k(W) \subset Z_k(X)$, see part (6) of Chow Homology, Lemma 18.2. For the second, let $W' \subset X \times \mathbf{P}^1$ be a closed subvariety of dimension $k + 1$ which dominates $\mathbf{P}^1$. We will show that $[W'_0]_k - [W'_\infty]_k$ is a principal divisor which will finish the proof. Let $W \subset X$ be the image of $W'$ under the projection to $X$. Then $W' \to W$ is proper and generically finite.

Let $f$ denote the projection $W' \to \mathbf{P}^1$ viewed as an element of $C(W')^*$. Let $g = \text{Nm}(f) \in C(W)^*$ be the norm. By Chow Homology, Lemma 18.1 we have

$$\text{div}_W(g) = \text{pr}_{X,*}\text{div}_{W'}(f)$$

Since it is clear that $\text{div}_{W'}(f) = [W'_0]_k - [W'_\infty]_k$ the proof is complete. \qed

10. Proper pushforward and rational equivalence

Suppose that $f : X \to Y$ is a proper morphism of varieties. Let $\alpha \sim_{\text{rat}} 0$ be a $k$-cycle on $X$ rationally equivalent to 0. Then the pushforward of $\alpha$ is rationally equivalent to zero: $f_*\alpha \sim_{\text{rat}} 0$. See Chapter I of [Ful98] or Chow Homology, Lemma 20.3.

Therefore we obtain a commutative diagram

$$
\begin{array}{ccc}
Z_k(X) & \longrightarrow & A_k(X) \\
| & f_* & | \\
Z_k(Y) & \longrightarrow & A_k(Y)
\end{array}
$$

of groups of $k$-cycles.

11. Flat pullback and rational equivalence

Suppose that $f : X \to Y$ is a flat morphism of varieties. Set $r = \dim(X) - \dim(Y)$. Let $\alpha \sim_{\text{rat}} 0$ be a $k$-cycle on $Y$ rationally equivalent to 0. Then the pullback of $\alpha$ is rationally equivalent to zero: $f^*\alpha \sim_{\text{rat}} 0$. See Chapter I of [Ful98] or Chow Homology, Lemma 20.2.

\[3\] If $W' \to W$ is birational, then the result follows from Chow Homology, Lemma 18.2. Our task is to show that even if $W' \to W$ has degree $> 1$ the basic rational equivalence $[W'_0]_k \sim_{\text{rat}} [W'_\infty]_k$ comes from a principal divisor on a subvariety of $X$. 

Therefore we obtain a commutative diagram

\[
\begin{array}{ccc}
Z_{k+r}(X) & \longrightarrow & A_{k+r}(X) \\
\uparrow f^* & & \uparrow f^* \\
Z_k(Y) & \longrightarrow & A_k(Y)
\end{array}
\]

of groups of \(k\)-cycles.

12. The short exact sequence for an open

Let \(X\) be a variety and let \(U \subset X\) be an open subvariety. Let \(X \setminus U = \bigcup Z_i\) be the decomposition into irreducible components. Then for each \(k \geq 0\) there exists a commutative diagram

\[
\begin{array}{ccc}
\bigoplus Z_k(Z_i) & \longrightarrow & Z_k(X) \longrightarrow Z_k(U) \longrightarrow 0 \\
\downarrow & & \downarrow & & \downarrow \\
\bigoplus A_k(Z_i) & \longrightarrow & A_k(X) \longrightarrow A_k(U) \longrightarrow 0
\end{array}
\]

with exact rows. Here the vertical arrows are the canonical quotient maps. The left horizontal arrows are given by proper pushforward along the closed immersions \(Z_i \to X\). The right horizontal arrows are given by flat pullback along the open immersion \(j : U \to X\). Since we have seen that these maps factor through rational equivalence we obtain the commutativity of the squares. The top row is exact simply because every subvariety of \(X\) is either contained in some \(Z_i\) or has irreducible intersection with \(U\). The bottom row is exact because every principal divisor \(\text{div}_W(f)\) on \(U\) is the restriction of a principal divisor on \(X\). More precisely, if \(W \subset U\) is a \((k+1)\)-dimensional closed subvariety and \(f \in \mathcal{C}(W)^*\), then denote \(\overline{W}\) the closure of \(W\) in \(X\). Then \(W \subset \overline{W}\) is an open immersion, so \(\mathcal{C}(W) = \mathcal{C}(\overline{W})\) and we may think of \(f\) as a nonconstant rational function on \(\overline{W}\). Then clearly

\[j^*\text{div}_\overline{W}(f) = \text{div}_W(f)\]

in \(Z_k(X)\). The exactness of the lower row follows easily from this. For details see Chow Homology, Lemma 19.2.

13. Proper intersections

0AZL First a few lemmas to get dimension estimates.

0AZM Lemma 13.1. Let \(X\) and \(Y\) be varieties. Then \(X \times Y\) is a variety and \(\dim(X \times Y) = \dim(X) + \dim(Y)\).

Proof. The scheme \(X \times Y = X \times_{\text{Spec}(\mathbb{C})} Y\) is a variety by Varieties, Lemma 3.3 The statement on dimension is Varieties, Lemma 20.5.

Recall that a regular immersion \(i : X \to Y\) of schemes is a closed immersion whose corresponding sheaf of ideals is locally generated by a regular sequence, see Divisors, Section 21. Moreover, the conormal sheaf \(\mathcal{C}_{X/Y}\) is finite locally free of rank equal to the length of the regular sequence. Let us say \(i\) is a regular immersion of codimension \(c\) if \(\mathcal{C}_{X/Y}\) is locally free of rank \(c\).

\[4\text{Since in this chapter we only consider Chow groups of varieties, we are prohibited from taking } Z_k(X \setminus U)\text{ and } A_k(X \setminus U), \text{ hence the approach using the varieties } Z_i.\]
More generally, recall (More on Morphisms, Section 52) that \( f : X \to Y \) is a local complete intersection morphism if we can cover \( X \) by opens \( U \) such that we can factor \( f|_U \) as

\[
\begin{array}{ccc}
U & \xrightarrow{i} & \mathbb{A}^n_Y \\
\downarrow & \searrow & \downarrow \\
Y & \xrightarrow{i} & Y
\end{array}
\]

where \( i \) is a Koszul regular immersion (if \( Y \) is locally Noetherian this is the same as asking \( i \) to be a regular immersion, see Divisors, Lemma [21.3]). Let us say that \( f \) is a local complete intersection morphism of relative dimension \( r \) if for any factorization as above, the closed immersion \( i \) has conormal sheaf of rank \( n - r \) (in other words if \( i \) is a Koszul-regular immersion of codimension \( n - r \) which in the Noetherian case just means it is regular immersion of codimension \( n - r \)).

**Lemma 13.2.** Let \( f : X \to Y \) be a morphism of varieties.

1. If \( Z \subset Y \) is a subvariety dimension \( d \) and \( f \) is a regular immersion of codimension \( c \), then every irreducible component of \( f^{-1}(Z) \) has dimension \( \geq d - c \).
2. If \( Z \subset Y \) is a subvariety of dimension \( d \) and \( f \) is a local complete intersection morphism of relative dimension \( r \), then every irreducible component of \( f^{-1}(Z) \) has dimension \( \geq d + r \).

**Proof.** Proof of (1). We may work locally, hence we may assume that \( Y = \text{Spec}(A) \) and \( X = V(f_1, \ldots, f_c) \) where \( f_1, \ldots, f_c \) is a regular sequence in \( A \). If \( Z = \text{Spec}(A/p) \), then we see that \( f^{-1}(Z) = \text{Spec}(A/p + (f_1, \ldots, f_c)) \). If \( V \) is an irreducible component of \( f^{-1}(Z) \), then we can choose a closed point \( v \in V \) not contained in any other irreducible component of \( f^{-1}(Z) \). Then

\[
\dim(Z) = \dim \mathcal{O}_{Z,v} \quad \text{and} \quad \dim(V) = \dim \mathcal{O}_{V,v} = \dim \mathcal{O}_{Z,v}/(f_1, \ldots, f_c)
\]

The first equality for example by Algebra, Lemma [115.1] and the second equality by our choice of closed point. The result now follows from the fact that dividing by one element in the maximal ideal decreases the dimension by at most 1, see Algebra, Lemma [59.12].

Proof of (2). Choose a factorization as in the definition of a local complete intersection and apply (1). Some details omitted.

**Lemma 13.3.** Let \( X \) be a nonsingular variety. Then the diagonal \( \Delta : X \to X \times X \) is a regular immersion of codimension \( \dim(X) \).

**Proof.** In fact, any closed immersion between nonsingular projective varieties is a regular immersion, see Divisors, Lemma [22.10].

The following lemma demonstrates how reduction to the diagonal works.

**Lemma 13.4.** Let \( X \) be a nonsingular variety and let \( W, V \subset X \) be closed subvarieties with \( \dim(W) = s \) and \( \dim(V) = r \). Then every irreducible component \( Z \) of \( V \cap W \) has dimension \( \geq r + s - \dim(X) \).

**Proof.** Since \( V \cap W = \Delta^{-1}(V \times W) \) (scheme theoretically) we conclude by Lemmas [13.3] and [13.2].

This lemma suggests the following definition.
Let $X$ be a nonsingular variety.

1. Let $W, V \subset X$ be closed subvarieties with $\dim(W) = s$ and $\dim(V) = r$. We say that $W$ and $V$ intersect properly if $\dim(V \cap W) \leq r + s - \dim(X)$.

2. Let $\alpha = \sum n_i [W_i]$ be an $s$-cycle, and $\beta = \sum m_j [V_j]$ be an $r$-cycle on $X$. We say that $\alpha$ and $\beta$ intersect properly if $W_i$ and $V_j$ intersect properly for all $i$ and $j$.

14. Intersection multiplicities using Tor formula

A basic fact we will use frequently is that given sheaves of modules $\mathcal{F}, \mathcal{G}$ on a ringed space $(X, \mathcal{O}_X)$ and a point $x \in X$ we have

$$\text{Tor}^{\mathcal{O}_X}_p (\mathcal{F}, \mathcal{G})_x = \text{Tor}^{\mathcal{O}_{X,x}}_p (\mathcal{F}_x, \mathcal{G}_x)$$

as $\mathcal{O}_{X,x}$-modules. This can be seen in several ways from our construction of derived tensor products in Cohomology, Section 27 for example it follows from Cohomology, Lemma 14.1. Moreover, if $X$ is a scheme and $\mathcal{F}$ and $\mathcal{G}$ are quasi-coherent, then the modules $\text{Tor}^{\mathcal{O}_X}_p (\mathcal{F}, \mathcal{G})$ are quasi-coherent too, see Derived Categories of Schemes, Lemma 14.2. More important for our purposes is the following result.

Let $X$ be a locally Noetherian scheme.

1. If $\mathcal{F}$ and $\mathcal{G}$ are coherent $\mathcal{O}_X$-modules, then $\text{Tor}^{\mathcal{O}_X}_p (\mathcal{F}, \mathcal{G})$ is too.

2. If $L$ and $K$ are in $D_{\text{Coh}}(\mathcal{O}_X)$, then so is $L \otimes_{\mathcal{O}_X} K$.

Proof. Let us explain how to prove (1) in a more elementary way and part (2) using previously developed general theory.

Proof of (1). Since formation of Tor commutes with localization we may assume $X$ is affine. Hence $X = \text{Spec}(A)$ for some Noetherian ring $A$ and $\mathcal{F}, \mathcal{G}$ correspond to finite $A$-modules $M$ and $N$ (Cohomology of Schemes, Lemma 9.1). By Derived Categories of Schemes, Lemma 3.9 we may compute the Tor’s by first computing the Tor’s of $M$ and $N$ over $A$, and then taking the associated $\mathcal{O}_X$-module. Since the modules $\text{Tor}^A_p (M, N)$ are finite by Algebra, Lemma 74.7 we conclude.

By Derived Categories of Schemes, Lemma 9.3 the assumption is equivalent to asking $L$ and $K$ to be (locally) pseudo-coherent. Then $L \otimes_{\mathcal{O}_X} K$ is pseudo-coherent by Cohomology, Lemma 11.5.

Let $X$ be a nonsingular variety. Let $\mathcal{F}, \mathcal{G}$ be coherent $\mathcal{O}_X$-modules. The $\mathcal{O}_X$-module $\text{Tor}^{\mathcal{O}_X}_p (\mathcal{F}, \mathcal{G})$ is coherent, has stalk at $x$ equal to $\text{Tor}^{\mathcal{O}_{X,x}}_p (\mathcal{F}_x, \mathcal{G}_x)$, is supported on $\text{Supp}(\mathcal{F}) \cap \text{Supp}(\mathcal{G})$, and is nonzero only for $p \in \{0, \ldots, \dim(X)\}$.

Proof. The result on stalks was discussed above and it implies the support condition. The Tor’s are coherent by Lemma 14.1. The vanishing of negative Tor’s is immediate from the construction. The vanishing of Tor$_p$ for $p > \dim(X)$ can be seen as follows: the local rings $\mathcal{O}_{X,x}$ are regular (as $X$ is nonsingular) of dimension $\leq \dim(X)$ (Algebra, Lemma 115.1), hence $\mathcal{O}_{X,x}$ has finite global dimension $\leq \dim(X)$ (Algebra, Lemma 109.8) which implies that Tor-groups of modules vanish beyond the dimension (More on Algebra, Lemma 63.19).

Let $X$ be a nonsingular variety and $W, V \subset X$ be closed subvarieties with $\dim(W) = s$ and $\dim(V) = r$. Assume $V$ and $W$ intersect properly. In this case Lemma 13.4 tells us all irreducible components of $V \cap W$ have dimension equal to $r + s - \dim(X)$. 

The sheaves $\text{Tor}^j_{\O_X}(\O_W, \O_V)$ are coherent, supported on $V \cap W$, and zero if $j < 0$ or $j > \dim(X)$ (Lemma 14.2). We define the intersection product as

$$W \cdot V = \sum_i (-1)^i [\text{Tor}^i_{\O_X}(\O_W, \O_V)]_{r + s - \dim(X)}.$$ 

We stress that this makes sense only because of our assumption that $V$ and $W$ intersect properly. This fact will necessitate a moving lemma in order to define the intersection product in general.

With this notation, the cycle $V \cdot W$ is a formal linear combination $\sum e_Z Z$ of the irreducible components $Z$ of the intersection $V \cap W$. The integers $e_Z$ are called the intersection multiplicities

$$e_Z = e(X, V \cdot W, Z) = \sum_i (-1)^i \text{length}_{\O_{X,Z}} \text{Tor}^i_{\O_{X,Z}}(\O_{W,Z}, \O_{V,Z})$$

where $\O_{X,Z}$, resp. $\O_{W,Z}$, resp. $\O_{V,Z}$ denotes the local ring of $X$, resp. $W$, resp. $V$ at the generic point of $Z$. These alternating sums of lengths of Tor’s satisfy many good properties, as we will see later on.

In the case of transversal intersections, the intersection number is 1.

**Lemma 14.3.** Let $X$ be a nonsingular variety. Let $V, W \subset X$ be closed subvarieties which intersect properly. Let $Z$ be an irreducible component of $V \cap W$ and assume that the multiplicity (in the sense of Section 4) of $Z$ in the closed subscheme $V \cap W$ is 1. Then $e(X, V \cdot W, Z) = 1$ and $V$ and $W$ are smooth in a general point of $Z$.

**Proof.** Let $(A, m, \kappa) = (\O_{X, \xi}, \m_\xi, \kappa(\xi))$ where $\xi \in Z$ is the generic point. Then $\dim(A) = \dim(X) - \dim(Z)$, see Varieties, Lemma 20.3. Let $I, J \subset A$ cut out the trace of $V$ and $W$ in Spec$(A)$. Set $\mathcal{I} = I + m^2/m^2$. Then $\dim(A, \mathcal{I}) \leq \dim(X) - \dim(V)$ with equality if and only if $A/\mathcal{I}$ is regular (this follows from the lemma cited above and the definition of regular rings, see Algebra, Definition 59.9 and the discussion preceding it). Similarly for $J$. If the multiplicity is 1, then $\text{length}_{A}(A/\mathcal{I} + J) = 1$, hence $I + J = m$, hence $\mathcal{I} + J = m/m^2$. Then we get equality everywhere (because the intersection is proper). Hence we find $f_1, \ldots, f_a \in I$ and $g_1, \ldots, g_b \in J$ such that $\mathcal{I}_1, \ldots, \mathcal{I}_b$ is a basis for $m/m^2$. Then $f_1, \ldots, g_b$ is a regular system of parameters and a regular sequence (Algebra, Lemma 105.3). The same lemma shows $A/(f_1, \ldots, f_a)$ is a regular local ring of dimension $\dim(X) - \dim(V)$, hence $A/(f_1, \ldots, f_a) \rightarrow A/I$ is an isomorphism (if the kernel is nonzero, then the dimension of $A/I$ is strictly less, see Algebra, Lemmas 105.2 and 59.12). We conclude $I = (f_1, \ldots, f_a)$ and $J = (g_1, \ldots, g_b)$ by symmetry. Thus the Koszul complex $K_*(A, f_1, \ldots, f_a)$ on $f_1, \ldots, f_a$ is a resolution of $A/I$, see More on Algebra, Lemma 29.2. Hence

$$\text{Tor}^A_p(A/I, A/J) = H_p(K_*(A, f_1, \ldots, f_a) \otimes_A A/J) = H_p(K_*(A/J, f_1 \mod J, \ldots, f_a \mod J))$$

Since we’ve seen above that $f_1 \mod J, \ldots, f_a \mod J$ is a regular system of parameters in the regular local ring $A/J$ we conclude that there is only one cohomology group, namely $H_0 = A/(I + J) = \kappa$. This finishes the proof. 

**Example 14.4.** In this example we show that it is necessary to use the higher tors in the formula for the intersection multiplicities above. Let $X$ be a nonsingular variety of dimension 4. Let $p \in X$ be a closed point. Let $V, W \subset X$ be closed subvarieties in $X$. Assume that there is an isomorphism

$$\O_{X,p} \cong \mathbb{C}[[x, y, z, w]]$$
such that the ideal of $V$ is $(xz, xw, yz, yw)$ and the ideal of $W$ is $(x - z, y - w)$. Then a computation shows that

$$\text{length } C[[x, y, z, w]]/(xz, xw, yz, yw, x - z, y - w) = 3$$

On the other hand, the multiplicity $e(X, V \cdot W, p) = 2$ as can be seen from the fact that formal locally $V$ is the union of two smooth planes $x = y = 0$ and $z = w = 0$ at $p$, each of which has intersection multiplicity 1 with the plane $x - z = y - w = 0$ (Lemma 14.3). To make an actual example, take a general morphism $f : \mathbb{P}^2 \to \mathbb{P}^4$ given by 5 homogeneous polynomials of degree $> 1$. The image $V \subset \mathbb{P}^4 = X$ will have singularities of the type described above, because there will be $p_1, p_2 \in \mathbb{P}^2$ with $f(p_1) = f(p_2)$. To find $W$ take a general plane passing through such a point.

15. Algebraic multiplicities

0AZU Let $(A, m, \kappa)$ be a Noetherian local ring. Let $M$ be a finite $A$-module and let $I \subset A$ be an ideal of definition (Algebra, Definition 58.1). Recall that the function

$$\chi_{I, M}(n) = \text{length}_A(M/I^nM) = \sum_{p=0, \ldots, n-1} \text{length}_A(I^pM/I^{p+1}M)$$

is a numerical polynomial (Algebra, Proposition 58.5). The degree of this polynomial is equal to $\text{dim}(\text{Supp}(M))$ by Algebra, Lemma 61.6.

0AZV **Definition 15.1.** In the situation above, if $d \geq \text{dim}(\text{Supp}(M))$, then we set $e_I(M, d)$ equal to 0 if $d > \text{dim}(\text{Supp}(M))$ and equal to $d!$ times the leading coefficient of the numerical polynomial $\chi_{I, M}$ so that

$$\chi_{I, M}(n) \sim e_I(M, d) \frac{n^d}{d!} + \text{lower order terms}$$

The multiplicity of $M$ for the ideal of definition $I$ is $e_I(M) = e_I(M, \text{dim}(\text{Supp}(M)))$.

0AZW **Lemma 15.2.** Let $A$ be a Noetherian local ring. Let $I \subset A$ be an ideal of definition. Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of finite $A$-modules. Let $d \geq \text{dim}(\text{Supp}(M))$. Then

$$e_I(M, d) = e_I(M', d) + e_I(M'', d)$$

**Proof.** Immediate from the definitions and Algebra, Lemma 58.10. □

0AZX **Lemma 15.3.** Let $A$ be a Noetherian local ring. Let $I \subset A$ be an ideal of definition. Let $M$ be a finite $A$-module. Let $d \geq \text{dim}(\text{Supp}(M))$. Then

$$e_I(M, d) = \sum_{p} \text{length}_{A_p}(M_p)e_I(A/p, d)$$

where the sum is over primes $p \subset A$ with $\text{dim}(A/p) = d$.

**Proof.** Both the left and side and the right hand side are additive in short exact sequences of modules of dimension $\leq d$, see Lemma 15.2 and Algebra, Lemma 51.3. Hence by Algebra, Lemma 61.1 it suffices to prove this when $M = A/q$ for some prime $q$ of $A$ with $\text{dim}(A/q) \leq d$. This case is obvious. □

0AZY **Lemma 15.4.** Let $P$ be a polynomial of degree $r$ with leading coefficient $a$. Then

$$r!a = \sum_{i=0, \ldots, r} (-1)^i \binom{r}{i} P(t - i)$$

for any $t$. 

Proof. Let us write $\Delta$ the operator which to a polynomial $P$ associates the polynomial $\Delta(P) = P(t) - P(t - 1)$. We claim that

$$\Delta^r(P) = \sum_{i=0}^r (-1)^i \binom{r}{i} P(t - i)$$

This is true for $r = 0, 1$ by inspection. Assume it is true for $r$. Then we compute

$$\Delta^{r+1}(P) = \sum_{i=0}^{r+1} (-1)^i \binom{r+1}{i} \Delta(P)(t - i)$$

$$= \sum_{n=-r,...,0} (-1)^i \binom{r}{i} (P(t - i) - P(t - i - 1))$$

Thus the claim follows from the equality

$$\binom{r+1}{i} = \binom{r}{i} + \binom{r}{i-1}$$

The lemma follows from the fact that $\Delta(P)$ is of degree $r - 1$ with leading coefficient $ra$ if the degree of $P$ is $r$. \qed

An important fact is that one can compute the multiplicity in terms of the Koszul complex. Recall that if $R$ is a ring and $f_1, \ldots, f_r \in R$, then $K_\bullet(f_1, \ldots, f_r)$ denotes the Koszul complex, see More on Algebra, Section 28.

0AZZ Theorem 15.5. Let $A$ be a Noetherian local ring. Let $I = (f_1, \ldots, f_r) \subset A$ be an ideal of definition. Let $M$ be a finite $A$-module. Then

$$e_I(M, r) = \sum (-1)^i \text{length}_A H_i(K_\bullet(f_1, \ldots, f_r) \otimes_A M)$$

Proof. Let us change the Koszul complex $K_\bullet(f_1, \ldots, f_r)$ into a cochain complex $K^\bullet$ by setting $K^n = K_{-n}(f_1, \ldots, f_r)$. Then $K^\bullet$ is sitting in degrees $-r, \ldots, 0$ and $H^i(K^\bullet \otimes_A M) = H_{-i}(K_\bullet(f_1, \ldots, f_r) \otimes_A M)$. The statement of the theorem makes sense as the modules $H^i(K^\bullet \otimes M)$ are annihilated by $f_1, \ldots, f_r$ (More on Algebra, Lemma 28.6) hence have finite length. Define a filtration on the complex $K^\bullet$ by setting

$$F^p(K^n \otimes_A M) = I^\max(0, p+n)(K^n \otimes_A M), \quad p \in \mathbb{Z}$$

Since $f_i I^p \subset I^{p+1}$ this is a filtration by subcomplexes. Thus we have a filtered complex and we obtain a spectral sequence, see Homology, Section 21. We have

$$E_0 = \bigoplus_{p,q} E_0^{p,q} = \bigoplus_{p,q} \text{gr}^p(K^{p+q} \otimes_A M) = \text{Gr}_I(K^\bullet \otimes_A M)$$

Since $K^n$ is finite free we have

$$\text{Gr}_I(K^\bullet \otimes_A M) = \text{Gr}_I(K^\bullet) \otimes_{\text{Gr}_I(A)} \text{Gr}_I(M)$$

Note that $\text{Gr}_I(K^\bullet)$ is the Koszul complex over $\text{Gr}_I(A)$ on the elements $\overline{f}_1, \ldots, \overline{f}_r \in I/I^2$. A simple calculation (omitted) shows that the differential $d_0$ on $E_0$ agrees with the differential coming from the Koszul complex. Since $\text{Gr}_I(M)$ is a finite $\text{Gr}_I(A)$-module and since $\text{Gr}_I(A)$ is Noetherian (as a quotient of $A/I[x_1, \ldots, x_r]$ with $x_i \mapsto \overline{f}_i$), the cohomology module $E_1 = \bigoplus E_1^{p,q}$ is a finite $\text{Gr}_I(A)$-module. However, as above $E_1$ is annihilated by $\overline{f}_1, \ldots, \overline{f}_r$. We conclude $E_1$ has finite length. In particular we find that $\text{Gr}_I^p(K^\bullet \otimes M)$ is acyclic for $p \gg 0$. 

INTERSECTION THEORY 12
Next, we check that the spectral sequence above converges using Homology, Lemma 21.10. The required equalities follow easily from the Artin-Rees lemma in the form stated in Algebra, Lemma 50.3. Thus we see that
\[ \sum (-1)^i \text{length}_A(H^i(K^\bullet \otimes_A M)) = \sum (-1)^p \text{length}_A(E_{p,q}^\infty) \]
because as we’ve seen above the length of $E_1$ is finite (of course this uses additivity of lengths). Pick $t$ so large that $\text{Gr}_p(F)(K^\bullet \otimes M)$ is acyclic for $p \geq t$ (see above). Using additivity again we see that
\[ \sum (-1)^p \text{length}_A(E_{p,q}^1) = \sum n \sum_{p \leq t} (-1)^n \text{length}_A(\text{gr}_p(K^n \otimes A M)) \]
This is equal to
\[ \sum_{n=-r,...,0} (-1)^n \binom{r}{n} \chi_{I,M}(t + n) \]
by our choice of filtration above and the definition of $\chi_{I,M}$ in Algebra, Section 58. The lemma follows from Lemma 15.4 and the definition of $e_I(M,r)$.

**Remark 15.6 (Trivial generalization).** Let $(A, m, \kappa)$ be a Noetherian local ring. Let $M$ be a finite $A$-module. Let $I \subset A$ be an ideal. The following are equivalent

1. $I' = I + \text{Ann}(M)$ is an ideal of definition (Algebra, Definition 58.1),
2. the image $\mathcal{I}$ of $I$ in $\overline{A} = A/\text{Ann}(M)$ is an ideal of definition,
3. $\text{Supp}(M/IM) \subset \{m\}$,
4. $\dim(\text{Supp}(M/IM)) \leq 0$, and
5. $\text{length}_A(M/IM) < \infty$.

This follows from Algebra, Lemma 61.3 (details omitted). If this is the case we have $M/I^n M = M/(I')^n M$ for all $n$ and $M/I^n M = M/\mathcal{I}^n M$ for all $n$ if $M$ is viewed as an $\overline{A}$-module. Thus we can define
\[ \chi_{I,M}(n) = \text{length}_A(M/I^n M) = \sum_{p=0,\ldots,n-1} \text{length}_A(IP^p M/IP^{p+1} M) \]
and we get
\[ \chi_{I,M}(n) = \chi_{I',M}(n) = \chi_{\mathcal{I},M}(n) \]
for all $n$ by the equalities above. All the results of Algebra, Section 58 and all the results in this section, have analogues in this setting. In particular we can define multiplicities $e_I(M,d)$ for $d \geq \dim(\text{Supp}(M))$ and we have
\[ \chi_{I,M}(n) \sim e_I(M,d) \frac{n^d}{d!} + \text{lower order terms} \]
as in the case where $I$ is an ideal of definition.

**16. Computing intersection multiplicities**

In this section we discuss some cases where the intersection multiplicities can be computed by different means. Here is a first example.

**Lemma 16.1.** Let $X$ be a nonsingular variety and $W, V \subset X$ closed subvarieties which intersect properly. Let $Z$ be an irreducible component of $V \cap W$ with generic point $\xi$. Assume that $\mathcal{O}_{W,\xi}$ and $\mathcal{O}_{V,\xi}$ are Cohen-Macaulay. Then
\[ e(X, V \cdot W, Z) = \text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{V \cap W,\xi}) \]
where $V \cap W$ is the scheme theoretic intersection. In particular, if both $V$ and $W$ are Cohen-Macaulay, then $V \cdot W = [V \cap W]_{\dim(V) + \dim(W) - \dim(X)}$.

**Proof.** Set $A = \mathcal{O}_{X, \xi}, B = \mathcal{O}_{W, \zeta}$, and $C = \mathcal{O}_{W, \zeta}$. By Auslander-Buchsbaum (Algebra, Proposition 110.1) we can find a finite free resolution $F_\bullet \to B$ of length
depth$(A) - \text{depth}(B) = \text{dim}(A) - \text{dim}(B) = \text{dim}(C)$

First equality as $A$ and $B$ are Cohen-Macaulay and the second as $V$ and $W$ intersect properly. Then $F_\bullet \otimes_A C$ is a complex of finite free modules representing $B \otimes_B^L C$ hence has cohomology modules with support in $\{m_A\}$. By the Acyclicity lemma (Algebra, Lemma 101.8) which applies as $C$ is Cohen-Macaulay we conclude that $F_\bullet \otimes_A C$ has nonzero cohomology only in degree $0$. This finishes the proof. \qed

**Lemma 16.2.** Let $A$ be a Noetherian local ring. Let $I = (f_1, \ldots, f_r)$ be an ideal generated by a regular sequence. Let $M$ be a finite $A$-module. Assume that $\text{dim}(\text{Supp}(M/IM)) = 0$. Then

e_1(M, r) = \sum (-1)^i \text{length}_A(\text{Tor}_i^A(A/I, M))

Here $e_1(M, r)$ is as in Remark 15.6.

**Proof.** Since $f_1, \ldots, f_r$ is a regular sequence the Koszul complex $K_\bullet(f_1, \ldots, f_r)$ is a resolution of $A/I$ over $A$, see More on Algebra, Lemma 29.7. Thus the right hand side is equal to

$$\sum (-1)^i \text{length}_A H_i(K_\bullet(f_1, \ldots, f_r) \otimes_A M)$$

Now the result follows immediately from Theorem 15.5 if $I$ is an ideal of definition. In general, we replace $A$ by $\overline{A} = A/\text{Ann}(M)$ and $f_1, \ldots, f_r$ by $\overline{f}_1, \ldots, \overline{f}_r$ which is allowed because

$$K_\bullet(f_1, \ldots, f_r) \otimes_A M = K_\bullet(\overline{f}_1, \ldots, \overline{f}_r) \otimes_{\overline{A}} M$$

Since $e_1(M, r) = e_1(M, r)$ where $\overline{I} = (\overline{f}_1, \ldots, \overline{f}_r) \subset \overline{A}$ is an ideal of definition the result follows from Theorem 15.5 in this case as well. \qed

**Lemma 16.3.** Let $X$ be a nonsingular variety. Let $W, V \subset X$ be closed subvarieties which intersect properly. Let $Z$ be an irreducible component of $V \cap W$ with generic point $\xi$. Suppose the ideal of $V$ in $\mathcal{O}_{X, \xi}$ is cut out by a regular sequence $f_1, \ldots, f_c \in \mathcal{O}_{X, \xi}$. Then $e(X, V \cdot W, Z)$ is equal to $c!$ times the leading coefficient in the Hilbert polynomial

$$t \mapsto \text{length}_{\mathcal{O}_{X, \xi}} \mathcal{O}_{W, \zeta}/(f_1, \ldots, f_c)^t, \quad t \gg 0.$$

In particular, this coefficient is $> 0$.

**Proof.** The equality

e(X, V \cdot W, Z) = e(f_1, \ldots, f_c)(\mathcal{O}_{W, \zeta}, c)

follows from the more general Lemma 16.2. To see that $e(f_1, \ldots, f_c)(\mathcal{O}_{W, \zeta}, c)$ is $> 0$ or equivalently that $e(f_1, \ldots, f_c)(\mathcal{O}_{W, \zeta}, c)$ is the leading coefficient of the Hilbert polynomial it suffices to show that the dimension of $\mathcal{O}_{W, \zeta}$ is $c$, because the degree of the Hilbert polynomial is equal to the dimension by Algebra, Proposition 15.8. Say $\dim(V) = r$, $\dim(W) = s$, and $\dim(X) = n$. Then $\dim(Z) = r + s - n$ as the intersection is proper. Thus the transcendence degree of $\kappa(\xi)$ over $C$ is $r + s - n$, see Algebra, Lemma 115.1. We have $r + c = n$ because $V$ is cut out by a regular
sequence in a neighbourhood of $\xi$, see Divisors, Lemma \[20.8\] and then Lemma \[13.2\] applies (for example). Thus
$$\dim(\mathcal{O}_{W,\xi}) = s - (r + s - n) = s - ((n - c) + s - n) = c$$
the first equality by Algebra, Lemma \[115.3\].

**Lemma 16.4.** In Lemma \[16.3\] assume that $c = 1$, i.e., $V$ is an effective Cartier divisor. Then
$$e(X, V \cdot W, Z) = \text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{W,\xi}/f_1 \mathcal{O}_{W,\xi}).$$

**Proof.** In this case the image of $f_1$ in $\mathcal{O}_{W,\xi}$ is nonzero by properness of intersection, hence a nonzerodivisor divisor. Moreover, $\mathcal{O}_{W,\xi}$ is a Noetherian local domain of dimension 1. Thus
$$\text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{W,\xi}/f_1 \mathcal{O}_{W,\xi}) = t \text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{W,\xi}/f_1 \mathcal{O}_{W,\xi})$$
for all $t \geq 1$, see Algebra, Lemma \[120.1\]. This proves the lemma.

**Lemma 16.5.** In Lemma \[16.3\] assume that the local ring $\mathcal{O}_{W,\xi}$ is Cohen-Macaulay. Then we have
$$e(X, V \cdot W, Z) = \text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{W,\xi}/f_1 \mathcal{O}_{W,\xi} + \ldots + f_c \mathcal{O}_{W,\xi}).$$

**Proof.** This follows immediately from Lemma \[16.1\]. Alternatively, we can deduce it from Lemma \[16.3\]. Namely, by Algebra, Lemma \[103.2\] we see that $f_1, \ldots, f_c$ is a regular sequence in $\mathcal{O}_{W,\xi}$. Then Algebra, Lemma \[68.2\] shows that $f_1, \ldots, f_c$ is a quasi-regular sequence. This easily implies the length of $\mathcal{O}_{W,\xi}/(f_1, \ldots, f_c)$
$$((c + t)/c) \text{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{W,\xi}/f_1 \mathcal{O}_{W,\xi} + \ldots + f_c \mathcal{O}_{W,\xi}).$$
Looking at the leading coefficient we conclude.

**17. Intersection product using Tor formula**

Let $X$ be a nonsingular variety. Let $\alpha = \sum n_i [W_i]$ be an $r$-cycle and $\beta = \sum m_j [V_j]$ be an $s$-cycle on $X$. Assume that $\alpha$ and $\beta$ intersect properly, see Definition \[13.5\].

In this case we define
$$\alpha \cdot \beta = \sum_{i,j} n_i m_j W_i \cdot V_j,$$
where $W_i \cdot V_j$ is as defined in Section \[14\]. If $\beta = [V]$ where $V$ is a closed subvariety of dimension $s$, then we sometimes write $\alpha \cdot \beta = \alpha \cdot V$.

**Lemma 17.1.** Let $X$ be a nonsingular variety. Let $a, b \in \mathbb{P}^1$ be distinct closed points. Let $k \geq 0$.

1. If $W \subset X \times \mathbb{P}^1$ is a closed subvariety of dimension $k + 1$ which intersects $X \times a$ properly, then
   (a) $[W_a]_k = W \cdot X \times a$ as cycles on $X \times \mathbb{P}^1$, and
   (b) $[W_a]_k = pr_{X,*}(W \cdot X \times a)$ as cycles on $X$.

2. Let $\alpha$ be a $(k + 1)$-cycle on $X \times \mathbb{P}^1$ which intersects $X \times a$ and $X \times b$ properly. Then $pr_{X,*}(\alpha \cdot X \times a - \alpha \cdot X \times b)$ is rationally equivalent to zero.

3. Conversely, any $k$-cycle which is rationally equivalent to 0 is of this form.
Proof. First we observe that $X \times a$ is an effective Cartier divisor in $X \times \mathbf{P}^1$ and that $W_\alpha$ is the scheme theoretic intersection of $W$ with $X \times a$. Hence the equality in (1)(a) is immediate from the definitions and the calculation of intersection multiplicity in case of a Cartier divisor given in Lemma \[\text{[6.4]}\]. Part (1)(b) holds because $W_\alpha \to X \times \mathbf{P}^1 \to X$ maps isomorphically onto its image which is how we viewed $W_\alpha$ as a closed subscheme of $X$ in Section \[\text{[8]}\]. Parts (2) and (3) are formal consequences of part (1) and the definitions. \[\square\]

For transversal intersections of closed subschemes the intersection multiplicity is 1.

\[\text{0B1J} \quad \text{Lemma 17.2.} \quad \text{Let } X \text{ be a nonsingular variety. Let } r, s \geq 0 \text{ and let } Y, Z \subset X \text{ be closed subschemes with } \dim(Y) \leq r \text{ and } \dim(Z) \leq s. \text{ Assume } [Y]_r = \sum n_i [Y_i] \text{ and } [Z]_s = \sum m_j [Z_j] \text{ intersect properly. Let } T \text{ be an irreducible component of } Y_{i_0} \cap Z_{j_0} \text{ for some } i_0 \text{ and } j_0 \text{ and assume that the multiplicity (in the sense of Section } \text{[7]}\text{) of } T \text{ in the closed subscheme } X \cap Z \text{ is } 1. \text{ Then}

(1) the coefficient of } T \text{ in } [Y]_r \cdot [Z]_s \text{ is } 1,

(2) } Y \text{ and } Z \text{ are nonsingular at the generic point of } Z,

(3) \quad \dim(Y_0) = 1, \quad m_{j_0} = 1, \quad \text{and}

(4) } T \text{ is not contained in } Y_i \text{ or } Z_j \text{ for } i \neq i_0 \text{ and } j \neq j_0.

\text{Proof.} \text{ Set } n = \dim(X), a = n - r, b = n - s. \text{ Observe that } \dim(T) = r + s - n = n - a - b \text{ by the assumption that the intersections are transversal. Let } (A, m, \kappa) = (O_{X, \xi}, m_\xi, \kappa(\xi)) \text{ where } \xi \in T \text{ is the generic point. Then } \dim(A) = a + b, \text{ see Varieties, Lemma \[\text{[20.3]}\]. Let } I_0, J_0, J \subset A \text{ cut out the trace of } Y_{i_0}, Y, Z_{j_0}, Z \text{ in } \text{Spec}(A). \text{ Then } \dim(A/I) = \dim(A/I_0) = b \text{ and } \dim(A/J) = \dim(A/J_0) = a \text{ by the same reference. Set } I = I + m^2/m^2. \text{ Then } I_0 \subset I_0 \subset m \text{ and } J \subset J_0 \subset m \text{ and } I + J = m. \text{ By Lemma \[\text{[14.3]}\] and its proof we see that } I_0 = (f_1, \ldots, f_a) \text{ and } J_0 = (g_1, \ldots, g_b) \text{ where } f_1, \ldots, g_b \text{ is a regular system of parameters for the regular local ring } A. \text{ Since } I + J = m, \text{ the map}

\[I \oplus J \to m/m^2 = \kappa f_1 \oplus \cdots \oplus \kappa f_a \oplus \kappa g_1 \oplus \cdots \oplus \kappa g_b\]

\text{is surjective. We conclude that we can find } f'_1, \ldots, f'_a \in I \text{ and } g'_1, \ldots, g'_b \in J \text{ whose residue classes in } m/m^2 \text{ are equal to the residue classes of } f_1, \ldots, f_a \text{ and } g_1, \ldots, g_b. \text{ Then } f'_1, \ldots, g'_b \text{ is a regular system of parameters of } A. \text{ By Algebra, Lemma \[\text{[105.3]}\] we find that } A/(f'_1, \ldots, f'_a) \text{ is a regular local ring of dimension } b. \text{ Thus any nontrivial quotient of } A/(f'_1, \ldots, f'_a) \text{ has strictly smaller dimension (Algebra, Lemmas \[\text{[105.2]}\] and \[\text{[59.12]}\]. Hence } I = (f'_1, \ldots, f'_a) = I_0. \text{ By symmetry } J = J_0. \text{ This proves (2), (3), and (4). Finally, the coefficient of } T \text{ in } [Y]_r \cdot [Z]_s \text{ is the coefficient of } T \text{ in } Y_{i_0} \cdot Z_{j_0} \text{ which is } 1 \text{ by Lemma \[\text{[14.3]}\]. \[\square\]}

18. Exterior product

\[\text{0B09} \quad \text{Let } X \text{ and } Y \text{ be varieties. Let } V, \text{ resp. } W \text{ be a closed subvariety of } X, \text{ resp. } Y. \text{ The product } V \times W \text{ is a closed subvariety of } X \times Y \text{ (Lemma \[\text{[13.1]}\]. For a } k\text{-cycle } \alpha = \sum n_i [V_i] \text{ and a } l\text{-cycle } \beta = \sum m_j [V_j] \text{ on } Y \text{ we define the exterior product of } \alpha \text{ and } \beta \text{ to be the cycle } \alpha \times \beta = \sum n_i m_j [V_i \times W_j]. \text{ Exterior product defines a } \mathbf{Z}\text{-linear map}

\[Z_r(X) \otimes \mathbf{Z} Z_s(Y) \to Z_{r+s}(X \times Y)\]

\text{Let us prove that exterior product factors through rational equivalence.}
Lemma 18.1. Let $X$ and $Y$ be varieties. Let $\alpha \in Z_r(X)$ and $\beta \in Z_s(Y)$. If $\alpha \sim_{rat} 0$ or $\beta \sim_{rat} 0$, then $\alpha \times \beta \sim_{rat} 0$.

Proof. By linearity and symmetry in $X$ and $Y$, it suffices to prove this when $\alpha = [V]$ for some subvariety $V \subset X$ of dimension $s$ and $\beta = [W_a]_a - [W_b]_b$ for some closed subvariety $W \subset Y \times \mathbb{P}^1$ of dimension $s+1$ which intersects $Y \times a$ and $Y \times b$ properly. In this case the lemma follows if we can prove

$$[(V \times W)_a]_{r+s} = [V] \times [W_a]$$

and similarly with $a$ replaced by $b$. Namely, then we see that $\alpha \times \beta = [(V \times W)_a]_{r+s} - [(V \times W)_b]_{r+s}$ as desired. To see the displayed equality we note the equality

$$V \times W_a = (V \times W)_a$$

of schemes. The projection $V \times W_a \to W_a$ induces a bijection of irreducible components (see for example Varieties, Lemma 8.4). Let $W' \subset W_a$ be an irreducible component with generic point $\zeta$. Then $V \times W'$ is the corresponding irreducible component of $V \times W_a$ (see Lemma 13.1). Let $\xi$ be the generic point of $V \times W'$. We have to show that

$$\text{length}_{\mathcal{O}_{V,\xi}}(\mathcal{O}_{W_a,\xi}) = \text{length}_{\mathcal{O}_{X \times Y,\zeta}}(\mathcal{O}_{V \times W_a,\xi})$$

In this formula we may replace $\mathcal{O}_{V,\xi}$ by $\mathcal{O}_{W_a,\xi}$ and we may replace $\mathcal{O}_{X \times Y,\zeta}$ by $\mathcal{O}_{V \times W_a,\xi}$ (see Algebra, Lemma 51.5). As $\mathcal{O}_{W_a,\xi} \to \mathcal{O}_{V \times W_a,\xi}$ is flat, by Algebra, Lemma 51.13 it suffices to show that

$$\text{length}_{\mathcal{O}_{V \times W_a,\xi}}(\mathcal{O}_{V \times W_a,\xi}/m_{\mathcal{O}_{V \times W_a,\xi}}) = 1$$

This is true because the quotient on the right is the local ring $\mathcal{O}_{V \times W',\xi}$ of a variety at a generic point hence equal to $k(\xi)$.

We conclude that exterior product defines a commutative diagram

$$\begin{array}{ccc}
Z_r(X) \otimes \mathbb{Z} Z_s(Y) & \longrightarrow & Z_{r+s}(X \times Y) \\
\downarrow & & \downarrow \\
A_r(X) \otimes \mathbb{Z} A_s(Y) & \longrightarrow & A_{r+s}(X \times Y)
\end{array}$$

for any pair of varieties $X$ and $Y$. For nonsingular varieties we can think of the exterior product as an intersection product of pullbacks.

Lemma 18.2. Let $X$ and $Y$ be nonsingular varieties. Let $\alpha \in Z_r(X)$ and $\beta \in Z_s(Y)$. Then

1. $\text{pr}_Y^*(\beta) = [X] \times \beta$ and $\text{pr}_X^*(\alpha) = \alpha \times [Y]$,
2. $\alpha \times [Y]$ and $[X] \times \beta$ intersect properly on $X \times Y$, and
3. we have $\alpha \times \beta = (\alpha \times [Y]) \cdot ([X] \times \beta) = \text{pr}_Y^*(\alpha) \cdot \text{pr}_X^*(\beta)$ in $Z_{r+s}(X \times Y)$.

Proof. By linearity we may assume $\alpha = [V]$ and $\beta = [W]$. Then (1) says that $\text{pr}_Y^{-1}(W) = X \times W$ and $\text{pr}_X^{-1}(V) = V \times Y$. This is clear. Part (2) holds because $X \times W \cap V \times Y = V \times W$ and $\dim(V \times W) = r + s$ by Lemma 13.1

Proof of (3). Let $\xi$ be the generic point of $V \times W$. Since the projections $X \times W \to W$ is smooth as a base change of $X \to \text{Spec}(\mathbb{C})$, we see that $X \times W$ is nonsingular at every point lying over the generic point of $W$, in particular at $\xi$. Similarly for $V \times Y$. Hence $\mathcal{O}_{X \times W,\xi}$ and $\mathcal{O}_{V \times Y,\xi}$ are Cohen-Macaulay local rings and Lemma...
16.1 applies. Since $V \times Y \cap X \times W = V \times W$ scheme theoretically the proof is complete. □

19. Reduction to the diagonal

Let $X$ be a nonsingular variety. We will use $\Delta$ to denote either the diagonal morphism $\Delta : X \to X \times X$ or the image $\Delta \subset X \times X$. Reduction to the diagonal is the statement that intersection products on $X$ can be reduced to intersection products of exterior products with the diagonal on $X \times X$.

Lemma 19.1. Let $X$ be a nonsingular variety.

(1) If $\mathcal{F}$ and $\mathcal{G}$ are coherent $\mathcal{O}_X$-modules, then there are canonical isomorphisms

$$\text{Tor}_i^{\mathcal{O}_{X \times X}}(\mathcal{O}_\Delta, \mathcal{F} \otimes_{\mathcal{O}_{X \times X}} \mathcal{G}) = \Delta, \text{Tor}_i^{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})$$

(2) If $K$ and $M$ are in $D_{QCoh}(\mathcal{O}_X)$, then there is a canonical isomorphism

$$L\Delta^* \left( L\mathcal{p}_1^* K \otimes_{\mathcal{O}_{X \times X}} L\mathcal{p}_2^* M \right) = K \otimes_{\mathcal{O}_X} M$$

in $D_{QCoh}(\mathcal{O}_X)$ and a canonical isomorphism

$$\mathcal{O}_\Delta \otimes_{\mathcal{O}_{X \times X}} L\mathcal{p}_1^* K \otimes_{\mathcal{O}_{X \times X}} L\mathcal{p}_2^* M = \Delta_* (K \otimes_{\mathcal{O}_X} M)$$

in $D_{QCoh}(X \times X)$.

Proof. Let us explain how to prove (1) in a more elementary way and part (2) using more general theory. As (2) implies (1) the reader can skip the proof of (1).

Proof of (1). Choose an affine open $\text{Spec}(A) \subset X$. Then $A$ is a Noetherian $\mathcal{C}$-algebra and $\mathcal{F}$, $\mathcal{G}$ correspond to finite $A$-modules $M$ and $N$ (Cohomology of Schemes, Lemma 9.1). By Derived Categories of Schemes, Lemma 3.9 we may compute $\text{Tor}_i^A(\mathcal{O}_X)$ by first computing the Tor’s of $M$ and $N$ over $A$, and then taking the associated $\mathcal{O}_X$-module. For the $\text{Tor}_i^A(\mathcal{O}_X)$ we compute the tor of $A$ and $M \otimes_{\mathcal{C}} N$ over $A \otimes_{\mathcal{C}} A$ and then take the associated $\mathcal{O}_{X \times X}$-module. Hence on this affine patch we have to prove that

$$\text{Tor}_i^{A \otimes_{\mathcal{C}} A}(A, M \otimes_{\mathcal{C}} N) = \text{Tor}_i^A(M, N)$$

To see this choose resolutions $F_\bullet \to M$ and $G_\bullet \to M$ by finite free $A$-modules (Algebra, Lemma 70.1). Note that $\text{Tot}(F_\bullet \otimes_{\mathcal{C}} G_\bullet)$ is a resolution of $M \otimes_{\mathcal{C}} N$ as it computes Tor groups over $\mathcal{C}$! Of course the terms of $F_\bullet \otimes_{\mathcal{C}} G_\bullet$ are finite free $A \otimes_{\mathcal{C}} A$-modules. Hence the left hand side of the displayed equation is the module

$$H_i(A \otimes_{A \otimes C} \text{Tot}(F_\bullet \otimes_{\mathcal{C}} G_\bullet))$$

and the right hand side is the module

$$H_i(\text{Tot}(F_\bullet \otimes_{A} G_\bullet))$$

Since $A \otimes_{A \otimes C} (F_q \otimes_{\mathcal{C}} G_q) = F_q \otimes_{A} G_q$ we see that these modules are equal. This defines an isomorphism over the affine open $\text{Spec}(A) \times \text{Spec}(A)$ (which is good enough for the application to equality of intersection numbers). We omit the proof that these isomorphisms glue.

Proof of (2). The second statement follows from the first by the projection formula as stated in Derived Categories of Schemes, Lemma 21.1. To see the first, represent $K$ and $M$ by K-flat complexes $K^\bullet$ and $M^\bullet$. Since pullback and tensor product
preserve K-flat complexes (Cohomology, Lemmas 27.5 and 27.7) we see that it suffices to show
\[ \Delta^* \text{Tot}(pr_1^* K \otimes_{\mathcal{O}_{X \times X}} pr_2^* M) = \text{Tot}(K \otimes_{\mathcal{O}_X} M) \]
Thus it suffices to see that there are canonical isomorphisms
\[ \Delta^* (pr_1^* K \otimes_{\mathcal{O}_{X \times X}} pr_2^* M) \rightarrow K \otimes_{\mathcal{O}_X} M \]
whenever \( K \) and \( M \) are \( \mathcal{O}_X \)-modules (not necessarily quasi-coherent or flat). We omit the details. □

Lemma 19.2. Let \( X \) be a nonsingular variety. Let \( \alpha, \beta \) be an \( r \)-cycle, resp. \( s \)-cycle on \( X \). Assume \( \alpha \) and \( \beta \) intersect properly. Then
1. \( \alpha \times \beta \) and \([\Delta] \) intersect properly
2. we have \( \Delta_*(\alpha \cdot \beta) = [\Delta] \cdot \alpha \times \beta \) as cycles on \( X \times X \),
3. if \( X \) is proper, then \( pr_{1,*}(\Delta \cdot \alpha \times \beta) = \alpha \cdot \beta \), where \( pr_1 : X \times X \rightarrow X \) is the projection.

Proof. By linearity it suffices to prove this when \( \alpha = [V] \) and \( \beta = [W] \) for some closed subvarieties \( V \subset X \) and \( W \subset Y \) which intersect properly. Recall that \( V \times W \) is a closed subvariety of dimension \( r + s \). Observe that scheme theoretically we have \( V \cap W = \Delta^{-1}(V \times W) \) as well as \( \Delta(V \cap W) = \Delta \cap V \times W \). This proves (1).

Proof of (2). Let \( Z \subset V \cap W \) be an irreducible component with generic point \( \xi \).
We have to show that the coefficient of \( Z \) in \( \alpha \cdot \beta \) is the same as the coefficient of \( \Delta(Z) \) in \([\Delta] \cdot \alpha \times \beta \).
The first is given by the integer
\[ \sum (-1)^i \text{length}_{\mathcal{O}_{X,\xi}} \text{Tor}_i^{\mathcal{O}_X}(\mathcal{O}_V, \mathcal{O}_W)_{\xi} \]
and the second by the integer
\[ \sum (-1)^i \text{length}_{\mathcal{O}_{X \times Y,\Delta(\xi)}} \text{Tor}_i^{\mathcal{O}_{X \times Y}}(\mathcal{O}_{\Delta}, \mathcal{O}_{V \times W})_{\Delta(\xi)} \]
However, by Lemma 19.1 we have
\[ \text{Tor}_i^{\mathcal{O}_X}(\mathcal{O}_V, \mathcal{O}_W)_{\xi} \cong \text{Tor}_i^{\mathcal{O}_{X \times Y}}(\mathcal{O}_{\Delta}, \mathcal{O}_{V \times W})_{\Delta(\xi)} \]
as \( \mathcal{O}_{X,\Delta(\xi)} \)-modules. Thus equality of lengths (by Algebra, Lemma 51.5 to be precise).
Part (2) implies (3) because \( pr_{1,*} \circ \Delta_* = \text{id} \) by Lemma 6.2. □

Proposition 19.3. Let \( X \) be a nonsingular variety. Let \( V \subset X \) and \( W \subset Y \) be closed subvarieties which intersect properly. Let \( Z \subset V \cap W \) be an irreducible component. Then \( e(X, V \cdot W, Z) > 0 \).

Proof. By Lemma 19.2 we have
\[ e(X, V \cdot W, Z) = e(X \times X, \Delta \cdot V \times W, \Delta(Z)) \]
Since \( \Delta : X \rightarrow X \times X \) is a regular immersion (see Lemma 13.3), we see that \( e(X \times X, \Delta \cdot V \times W, \Delta(Z)) \) is a positive integer by Lemma 16.3. □

This is one of the main results of [Ser65].

The following is a key lemma in the development of the theory as is done in this chapter. Essentially, this lemma tells us that the intersection numbers have a suitable additivity property.
Lemma 19.4. Let $X$ be a nonsingular variety. Let $\mathcal{F}$ and $\mathcal{G}$ be coherent sheaves on $X$ with $\dim(\text{Supp}(\mathcal{F})) \leq r$, $\dim(\text{Supp}(\mathcal{G})) \leq s$, and $\dim(\text{Supp}(\mathcal{F}) \cap \text{Supp}(\mathcal{G})) \leq r + s - \dim X$. In this case $[\mathcal{F}]_r$ and $[\mathcal{G}]_s$ intersect properly and

$$[\mathcal{F}]_r \cdot [\mathcal{G}]_s = \sum (-1)^p [\text{Tor}_p^{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})]_{r+s-\dim(X)}.$$

Proof. The statement that $[\mathcal{F}]_r$ and $[\mathcal{G}]_s$ intersect properly is immediate. Since we are proving an equality of cycles we may work locally on $X$. (Observe that the formation of the intersection product of cycles, the formation of Tor-sheaves, and forming the cycle associated to a coherent sheaf, each commute with restriction to open subschemes.) Thus we may and do assume that $X$ is affine.

Denote $\text{RHS}(\mathcal{F}, \mathcal{G}) = [\mathcal{F}]_r \cdot [\mathcal{G}]_s$ and $\text{LHS}(\mathcal{F}, \mathcal{G}) = \sum (-1)^p [\text{Tor}_p^{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})]_{r+s-\dim(X)}$.

Consider a short exact sequence

$$0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0$$

of coherent sheaves on $X$ with $\text{Supp}(\mathcal{F}_i) \subset \text{Supp}(\mathcal{F})$, then both $\text{LHS}(\mathcal{F}_i, \mathcal{G})$ and $\text{RHS}(\mathcal{F}_i, \mathcal{G})$ are defined for $i = 1, 2, 3$ and we have

$$\text{RHS}(\mathcal{F}_2, \mathcal{G}) = \text{RHS}(\mathcal{F}_1, \mathcal{G}) + \text{RHS}(\mathcal{F}_3, \mathcal{G})$$

and similarly for LHS. Namely, the support condition guarantees that everything is defined, the short exact sequence and additivity of lengths gives

$$[\mathcal{F}_2]_r = [\mathcal{F}_1]_r + [\mathcal{F}_3]_r$$

(Chow Homology, Lemma 10.4) which implies additivity for RHS. The long exact sequence of Tors

$$\ldots \to \text{Tor}_1(\mathcal{F}_3, \mathcal{G}) \to \text{Tor}_0(\mathcal{F}_1, \mathcal{G}) \to \text{Tor}_0(\mathcal{F}_2, \mathcal{G}) \to \text{Tor}_0(\mathcal{F}_3, \mathcal{G}) \to 0$$

and additivity of lengths as before implies additivity for LHS.

By Algebra, Lemma 61.1 and the fact that $X$ is affine, we can find a filtration of $\mathcal{F}$ whose graded pieces are structure sheaves of closed subvarieties of $\text{Supp}(\mathcal{F})$. The additivity shown in the previous paragraph, implies that it suffices to prove $\text{LHS} = \text{RHS}$ with $\mathcal{F}$ replaced by $\mathcal{O}_V$ where $V \subset \text{Supp}(\mathcal{F})$. By symmetry we can do the same for $\mathcal{G}$. This reduces us to proving that

$$\text{LHS}(\mathcal{O}_V, \mathcal{O}_W) = \text{RHS}(\mathcal{O}_V, \mathcal{O}_W)$$

where $W \subset \text{Supp}(\mathcal{G})$ is a closed subvariety. If $\dim(V) = r$ and $\dim(W) = s$, then this equality is the definition of $V \cdot W$. On the other hand, if $\dim(V) < r$ or $\dim(W) < s$, i.e., $[V]_r = 0$ or $[W]_s = 0$, then we have to prove that $\text{RHS}(\mathcal{O}_V, \mathcal{O}_W) = 0$.

Let $Z \subset V \cap W$ be an irreducible component of dimension $r+s-\dim(X)$. This is the maximal dimension of a component and it suffices to show that the coefficient of $Z$ in RHS is zero. Let $\xi \in Z$ be the generic point. Write $A = \mathcal{O}_{X,\xi}$, $B = \mathcal{O}_{X \times X, \Delta(\xi)}$, and $C = \mathcal{O}_{V \times W, \Delta(\xi)}$. By Lemma 19.1, we have

$$\text{coeff of } Z \text{ in } \text{RHS}(\mathcal{O}_V, \mathcal{O}_W) = \sum (-1)^i \text{length}_B \text{Tor}_i^B(A, C)$$

The reader can see that this is not a triviality by taking $r = s = 1$ and $X$ a nonsingular surface and $V = W$ a closed point $x$ of $X$. In this case there are 3 nonzero Tors of lengths 1, 2, 1 at $x$. 

---

\footnote{The reader can see that this is not a triviality by taking $r = s = 1$ and $X$ a nonsingular surface and $V = W$ a closed point $x$ of $X$. In this case there are 3 nonzero Tors of lengths 1, 2, 1 at $x$.}
Since \( \dim(V) < r \) or \( \dim(W) < s \) we have \( \dim(V \times W) < r + s \) which implies \( \dim(C) < \dim(X) \) (small detail omitted). Moreover, the kernel \( I \) of \( B \to A \) is generated by a regular sequence of length \( \dim(X) \) (Lemma 13.3). Hence vanishing by Lemma 16.2 because the Hilbert function of \( C \) with respect to \( I \) has degree \( \dim(C) < n \) by Algebra, Proposition 59.8.

**Remark 19.5.** Let \((A, m, \kappa)\) be a regular local ring. Let \( M \) and \( N \) be nonzero finite \( A \)-modules such that \( M \otimes_A N \) is supported in \( \{m\} \). Then

\[
\chi(M, N) = \sum (-1)^i \text{length}_A \text{Tor}_i^A(M, N)
\]

is finite. Let \( r = \dim(\text{Supp}(M)) \) and \( s = \dim(\text{Supp}(N)) \). In [Ser65] it is shown that \( r + s \leq \dim(A) \) and the following conjectures are made:

1. If \( r + s < \dim(A) \), then \( \chi(M, N) = 0 \), and
2. If \( r + s = \dim(A) \), then \( \chi(M, N) > 0 \).

The arguments that prove Lemma 19.4 and Proposition 19.3 can be leveraged (as is done in Serre’s text) to show that (1) and (2) are true if \( A \) contains a field. Currently, conjecture (1) is known in general and it is known that \( \chi(M, N) \geq 0 \) in general (Gabber). Positivity is, as far as we know, still an open problem.

## 20. Associativity of intersections

**Lemma 20.1.** Let \( X \) be a nonsingular variety. Let \( U, V, W \) be closed subvarieties. Assume that \( U, V, W \) intersect properly pairwise and that \( \dim(U \cap V \cap W) \leq \dim(U) + \dim(V) + \dim(W) - 2 \dim(X) \). Then

\[
U \cdot (V \cdot W) = (U \cdot V) \cdot W
\]

as cycles on \( X \).

**Proof.** We are going to use Lemma 19.4 without further mention. This implies that

\[
V \cdot W = \sum (-1)^i \text{length}_A \text{Tor}_i^A(O_V, O_W)
\]

\[
U \cdot (V \cdot W) = \sum (-1)^{i+j} \text{length}_A \text{Tor}_{i+j}^A(O_U, \text{Tor}_i(O_V, O_W))
\]

\[
U \cdot V = \sum (-1)^i \text{length}_A \text{Tor}_i(O_U, O_V)
\]

\[
(U \cdot V) \cdot W = \sum (-1)^{i+j} \text{length}_A \text{Tor}_{i+j}(\text{Tor}_i(O_U, O_V), O_W)
\]

where \( \dim(U) = a \), \( \dim(V) = b \), \( \dim(W) = c \), \( \dim(X) = n \). The assumptions in the lemma guarantee that the coherent sheaves in the formulae above satisfy the required bounds on dimensions of supports in order to make sense of these. Now consider the object

\[
K = O_U \otimes_{O_X}^L O_V \otimes_{O_X}^L O_W
\]

of the derived category \( D_{\text{coh}}(O_X) \). We claim that the expressions obtained above for \( U \cdot (V \cdot W) \) and \( (U \cdot V) \cdot W \) are equal to

\[
\sum (-1)^k H^k(K)
\]

This will prove the lemma. By symmetry it suffices to prove one of these equalities. To do this we represent \( O_U \) and \( O_V \otimes_{O_X}^L O_W \) by K-flat complexes \( M^\bullet \) and \( L^\bullet \) and
use the spectral sequence associated to the double complex \( K^\bullet \otimes_{\mathcal{O}_X} L^\bullet \) in Homology, Section 22. This is a spectral sequence with \( E_2^{p,q} = \text{Tor}_{-p}(\mathcal{O}_U, \text{Tor}_{-q}(\mathcal{O}_V, \mathcal{O}_W)) \)
converging to \( H^{p+q}(K) \) (details omitted; compare with More on Algebra, Example 60.4). Since lengths are additive in short exact sequences we see that the result is true. \( \square \)

21. Flat pullback and intersection products

\begin{lemma}
Let \( f : X \to Y \) be a flat morphism of nonsingular varieties. Set \( e = \dim(X) - \dim(Y) \). Let \( \mathcal{F} \) and \( \mathcal{G} \) be coherent sheaves on \( Y \) with \( \dim(\text{Supp}(\mathcal{F})) \leq r \), \( \dim(\text{Supp}(\mathcal{G})) \leq s \), and \( \dim(\text{Supp}(\mathcal{F}) \cap \text{Supp}(\mathcal{G})) \leq r + s - \dim(Y) \). In this case the cycles \( [f^*\mathcal{F}]_{r+e} \) and \( [f^*\mathcal{G}]_{s+e} \) intersect properly and
\[
f^*([\mathcal{F}]_r : [\mathcal{G}]_s) = [f^*\mathcal{F}]_{r+e} \cdot [f^*\mathcal{G}]_{s+e}
\]

\textbf{Proof.} The statement that \( [f^*\mathcal{F}]_{r+e} \) and \( [f^*\mathcal{G}]_{s+e} \) intersect properly is immediate from the assumption that \( f \) has relative dimension \( e \). By Lemmas 19.4 and 7.4 it suffices to show that
\[
f^*\text{Tor}_1^{\mathcal{O}_Y}(\mathcal{F}, \mathcal{G}) = \text{Tor}_1^{\mathcal{O}_X}(f^*\mathcal{F}, f^*\mathcal{G})
\]
as \( \mathcal{O}_X \)-modules. This follows from Cohomology, Lemma 28.3 and the fact that \( f^* \) is exact, so \( Lf^*\mathcal{F} = f^*\mathcal{F} \) and similarly for \( \mathcal{G} \). \( \square \)

\begin{lemma}
Let \( f : X \to Y \) be a flat morphism of nonsingular varieties. Let \( \alpha \) be a \( r \)-cycle on \( Y \) and \( \beta \) an \( s \)-cycle on \( Y \). Assume that \( \alpha \) and \( \beta \) intersect properly. Then \( f^*\alpha \) and \( f^*\beta \) intersect properly and \( f^*(\alpha \cdot \beta) = f^*\alpha \cdot f^*\beta \).

\textbf{Proof.} By linearity we may assume that \( \alpha = [V] \) and \( \beta = [W] \) for some closed subvarieties \( V, W \subseteq Y \) of dimension \( r, s \). Say \( f \) has relative dimension \( e \). Then the lemma is a special case of Lemma 21.1 because \( [V] = [\mathcal{O}_V]_r, [W] = [\mathcal{O}_W]_r, f^*[V] = [f^{-1}(V)]_{r+e} = [f^*\mathcal{O}_V]_{r+e}, \) and \( f^*[W] = [f^{-1}(W)]_{s+e} = [f^*\mathcal{O}_W]_{s+e}. \) \( \square \)

22. Projection formula for flat proper morphisms

\begin{lemma}
Let \( f : X \to Y \) be a flat proper morphism of nonsingular varieties. Set \( e = \dim(X) - \dim(Y) \). Let \( \alpha \) be an \( r \)-cycle on \( X \) and let \( \beta \) be an \( s \)-cycle on \( Y \). Assume that \( \alpha \) and \( f^*(\beta) \) intersect properly. Then \( f_*(\alpha) \) and \( \beta \) intersect properly and
\[
f_*(\alpha) \cdot \beta = f_*(\alpha \cdot f^*\beta)
\]

\textbf{Proof.} By linearity we reduce to the case where \( \alpha = [V] \) and \( \beta = [W] \) for some closed subvariety \( V \subseteq X \) and \( W \subseteq Y \) of dimension \( r \) and \( s \). Then \( f^{-1}(W) \) has pure dimension \( s + e \). We assume the cycles \( [V] \) and \( f^*[W] \) intersect properly. We will use without further mention the fact that \( V \cap f^{-1}(W) \to f(V) \cap W \) is surjective. Let \( a \) be the dimension of the generic fibre of \( V \to f(V) \). If \( a > 0 \), then \( f_*[V] = 0 \). In particular \( f_\alpha \) and \( \beta \) intersect properly. To finish this case we have to show that \( f_*([V] \cdot f^*[W]) = 0 \). However, since every fibre of \( V \to f(V) \) has dimension \( \geq a \) (see Morphisms, Lemma 27.4) we conclude that every irreducible component \( Z \) of

See Serre, Chapter V, Section 7, formula (10) for a more general formula.
$V \cap f^{-1}(W)$ has fibres of dimension $\geq a$ over $f(Z)$. This certainly implies what we want.

Assume that $V \to f(V)$ is generically finite. Let $Z \subset f(V) \cap W$ be an irreducible component. Let $Z_i \subset V \cap f^{-1}(W)$, $i = 1, \ldots, t$ be the irreducible components of $V \cap f^{-1}(W)$ dominating $Z$. By assumption each $Z_i$ has dimension $r + s + e - \dim(X) = r + s - \dim(Y)$. Hence $\dim(Z) \leq r + s - \dim(Y)$. Thus we see that $f(V)$ and $W$ intersect properly, $\dim(Z) = r + s - \dim(Y)$, and each $Z_i \to Z$ is generically finite. In particular, it follows that $V \to f(V)$ has finite fibre over the generic point $\xi$ of $Z$. Thus $V \to Y$ is finite in an open neighbourhood of $\xi$, see Cohomology of Schemes, Lemma 22.2. Using a very general projection formula\footnote{This can be avoided by working in an affine neighbourhood of $\xi$ as above, choosing an affine open of $X$ containing the generic points of the $Z_i$, and translating the question into algebra. Doing this will produce a relatively elementary proof of (22.1.1).} for derived tensor products, we get

$$Rf_*(O_V \otimes_{O_X} Lf^*O_W) = Rf_*O_V \otimes_{O_Y} O_W$$

see Derived Categories of Schemes, Lemma 21.1. Since $f$ is flat, we see that $Lf^*O_W = f^*O_W$. Since $f|_V$ is finite in an open neighbourhood of $\xi$ we have

$$(Rf_*F)_\xi = (f_*F)_\xi$$

for any coherent sheaf on $X$ whose support is contained in $V$ (see Cohomology of Schemes, Lemma 20.8). Thus we conclude that

0B11 (22.1.1) $$\left(f_*\text{Tor}_i^{O_X}(O_Y, f^*O_W)\right)_\xi = \left(\text{Tor}_i^{O_Y}(f_*O_Y, O_W)\right)_\xi$$

for all $i$. Since $f^*[W] = [f^*O_W]_{r+s}$ by Lemma 7.1 we have

$$[V] \cdot f^*[W] = \sum (-1)^i [\text{Tor}_i^{O_X}(O_Y, f^*O_W)]_{r+s-\dim(Y)}$$

by Lemma 19.4. Applying Lemma 6.1 we find

$$f_*([V] \cdot f^*[W]) = \sum (-1)^i [f_*\text{Tor}_i^{O_X}(O_Y, f^*O_W)]_{r+s-\dim(Y)}$$

Since $f_*[V] = [f_*O_Y]_r$ by Lemma 6.1 we have

$$[f_*V] \cdot [W] = \sum (-1)^i [f_*\text{Tor}_i^{O_X}(O_Y, O_W)]_{r+s-\dim(Y)}$$

again by Lemma 19.4. Comparing the formula for $f_*([V] \cdot f^*[W])$ with the formula for $f_*[V] \cdot [W]$ and looking at the coefficient of $Z$ by taking lengths of stalks at $\xi$, we see that (22.1.1) finishes the proof. \qed

0B1M \begin{lemma}
Let $X \to P$ be a closed immersion of nonsingular varieties. Let $C' \subset P \times P^1$ be a closed subvariety of dimension $r + 1$. Assume

1. the fibre $C = C'_0$ has dimension $r$, i.e., $C' \to P^1$ is dominant,
2. $C'$ intersects $X \times P^1$ properly,
3. $[C]_r$ intersects $X$ properly.

Then setting $\alpha = [C]_r : X$ viewed as cycle on $X$ and $\beta = C' \cdot X \times P_1$ viewed as cycle on $X \times P^1$, we have

$$\alpha = pr_{X,*}(\beta : X \times 0)$$

as cycles on $X$ where $pr_X : X \times P^1 \to X$ is the projection.
\end{lemma}
Proof. Let $pr : P \times \mathbb{P}^1 \to P$ be the projection. Since we are proving an equality of cycles it suffices to think of $\alpha$, resp. $\beta$ as a cycle on $P$, resp. $P \times \mathbb{P}^1$ and prove the result for pushing forward by $pr$. Because $pr^*X = X \times \mathbb{P}^1$ and $pr$ defines an isomorphism of $C'_0$ onto $C$ the projection formula (Lemma 22.1) gives

$$pr_*( [C'_0] \cdot X \times \mathbb{P}^1) = [C] \cdot X = \alpha$$

On the other hand, we have $[C'_0] = C' \cdot P \times 0$ as cycles on $P \times \mathbb{P}^1$ by Lemma 17.1. Hence

$$[C'_0] \cdot X = (C' \cdot P \times 0) \cdot X \times \mathbb{P}^1 = (C' \cdot X \times \mathbb{P}^1) \cdot P \times 0$$

by associativity (Lemma 20.1) and commutativity of the intersection product. It remains to show that the intersection product of $C' \cdot X \times \mathbb{P}^1$ with $P \times 0$ on $P \times \mathbb{P}^1$ is equal (as a cycle) to the intersection product of $\beta$ with $X \times 0$ on $X \times \mathbb{P}^1$. Write $C' \cdot X \times \mathbb{P}^1 = \sum n_k[E_k]$ and hence $\beta = \sum n_k[E_k]$ for some subvarieties $E_k \subset X \times \mathbb{P}^1 \subset P \times \mathbb{P}^1$. Then both intersections are equal to $\sum m_k[E_{k,0}]$ by Lemma 17.1 applied twice. This finishes the proof. \qed

23. Projections

Recall that we are working over a fixed algebraically closed ground field $\mathbf{C}$. If $V$ is a finite dimensional vector space over $\mathbf{C}$ then we set

$$\mathbf{P}(V) = \text{Proj}(\text{Sym}(V))$$

where $\text{Sym}(V)$ is the symmetric algebra on $V$ over $\mathbf{C}$. The normalization is chosen such that $V = \Gamma(\mathbf{P}(V), \mathcal{O}_{\mathbf{P}(V)}(1))$. Of course we have $\mathbf{P}(V) \cong \mathbf{P}^n_{\mathbf{C}}$ if $\dim(V) = n + 1$. We note that $\mathbf{P}(V)$ is a nonsingular projective variety.

Let $p \in \mathbf{P}(V)$ be a closed point. The point $p$ corresponds to a surjection $V \to L_p$ of vector spaces where $\dim(L_p) = 1$, see Constructions, Lemma 12.3. Let us denote $W_p = \text{Ker}(V \to L_p)$. Projection from $p$ is the morphism

$$r_p : \mathbf{P}(V) \setminus \{p\} \to \mathbf{P}(W_p)$$

of Constructions, Lemma 11.1. Here is a lemma to warm up.

Lemma 23.1. Let $V$ be a vector space of dimension $n + 1$. Let $X \subset \mathbf{P}(V)$ be a closed subscheme. If $X \neq \mathbf{P}(V)$, then there is a nonempty Zariski open $U \subset \mathbf{P}(V)$ such that for all closed points $p \in U$ the restriction of the projection $r_p$ defines a finite morphism $r_p|_X : X \to \mathbf{P}(W_p)$.

Proof. We claim the lemma holds with $U = \mathbf{P}(V) \setminus X$. For a closed point $p$ of $U$ we indeed obtain a morphism $r_p|_X : X \to \mathbf{P}(W_p)$. This morphism is proper because $X$ is a proper scheme (Morphisms, Lemmas 41.5 and 39.7). On the other hand, the fibres of $r_p$ are affine lines as can be seen by a direct calculation. Hence the fibres of $r_p|_X$ are proper and affine, whence finite (Morphisms, Lemma 42.11). Finally, a proper morphism with finite fibres is finite (Cohomology of Schemes, Lemma 21.1). \qed

Lemma 23.2. Let $V$ be a vector space of dimension $n + 1$. Let $X \subset \mathbf{P}(V)$ be a closed subvariety. Let $x \in X$ be a nonsingular point.

1. If $\dim(X) < n - 1$, then there is a nonempty Zariski open $U \subset \mathbf{P}(V)$ such that for all closed points $p \in U$ the morphism $r_p|_X : X \to r_p(X)$ is an isomorphism over an open neighbourhood of $r_p(x)$.
(2) If \( \dim(X) = n - 1 \), then there is a nonempty Zariski open \( U \subset \mathbf{P}(V) \) such that for all closed points \( p \in U \) the morphism \( r_p|_X : X \to \mathbf{P}(W_p) \) is étale at \( x \).

**Proof.** Proof of (1). Note that if \( x, y \in X \) have the same image under \( r_p \) then \( p \) is on the line \( \overline{xy} \). Consider the finite type scheme

\[
T = \{(y, p) \mid y \in X \setminus \{x\}, \ p \in \mathbf{P}(V), \ p \in \overline{xy}\}
\]

and the morphisms \( T \to X \) and \( T \to \mathbf{P}(V) \) given by \( (y, p) \mapsto y \) and \( (y, p) \mapsto p \).

Since each fibre of \( T \to X \) is a line, we see that the dimension of \( T \) is \( \dim(X) + 1 < \dim(\mathbf{P}(V)) \). Hence \( T \to \mathbf{P}(V) \) is not surjective. On the other hand, consider the finite type scheme

\[
T' = \{p \mid p \in \mathbf{P}(V) \setminus \{x\}, \ \overline{xy} \text{ tangent to } X \text{ at } x\}
\]

Then the dimension of \( T' \) is \( \dim(X) < \dim(\mathbf{P}(V)) \). Thus the morphism \( T' \to \mathbf{P}(V) \) is not surjective either. Let \( U \subset \mathbf{P}(V) \setminus X \) be nonempty open and disjoint from these images; such a \( U \) exists because the images of \( T \) and \( T' \) in \( \mathbf{P}(V) \) are constructible by Morphisms, Lemma 21.2. Then for \( p \in U \) closed the projection \( r_p|_X : X \to \mathbf{P}(W_p) \) is injective on the tangent space at \( x \) and \( r_p^{-1}(\{p(x)\}) = \{x\} \).

This means that \( r_p \) is unramified at \( x \) (Varieties, Lemma 16.8), finite by Lemma 23.3. Thus \( \mathbf{P}(r_p(x)) \) is étale, otherwise \( \mathbf{P}(r_p(x)) \) is not surjective. Proving (1).

Proof of (2). In this case we still conclude that the morphism \( T' \to \mathbf{P}(V) \) is not surjective. Arguing as above we conclude that for \( U \subset \mathbf{P}(V) \) avoiding \( X \) and the image of \( T' \), the projection \( r_p|_X : X \to \mathbf{P}(W_p) \) is étale at \( x \) and finite. \( \square \)

**Lemma 23.3.** Let \( V \) be a vector space of dimension \( n + 1 \). Let \( Y, Z \subset \mathbf{P}(V) \) be closed subvarieties. There is a nonempty Zariski open \( U \subset \mathbf{P}(V) \) such that for all closed points \( p \in U \) we have

\[
Y \cap r_p^{-1}(r_p(Z)) = (Y \cap Z) \cup E
\]

with \( E \subset Y \) closed and \( \dim(E) \leq \dim(Y) + \dim(Z) + 1 - n \).

**Proof.** Set \( Y' = Y \setminus Y \cap Z \). Let \( y \in Y', z \in Z \) be closed points with \( r_p(y) = r_p(z) \). Then \( p \) is on the line \( \overline{yz} \) passing through \( y \) and \( z \). Consider the finite type scheme

\[
T = \{(y, z, p) \mid y \in Y', z \in Z, p \in \overline{yz}\}
\]

and the morphism \( T \to \mathbf{P}(V) \) given by \( (y, z, p) \mapsto p \). Observe that \( T \) is irreducible and that \( \dim(T) = \dim(Y) + \dim(Z) + 1 \). Hence the general fibre of \( T \to \mathbf{P}(V) \) has dimension at most \( \dim(Y) + \dim(Z) + 1 - n \), more precisely, there exists a nonempty open \( U \subset \mathbf{P}(V) \setminus (Y \cup Z) \) over which the fibre has dimension at most \( \dim(Y) + \dim(Z) + 1 - n \) (Varieties, Lemma 20.4). Let \( p \in U \) be a closed point and let \( F \subset T \) be the fibre of \( T \to \mathbf{P}(V) \) over \( p \). Then

\[
(Y \cap r_p^{-1}(r_p(Z))) \setminus (Y \cap Z)
\]

is the image of \( F \to Y \), \( (y, z, p) \mapsto y \). Again by Varieties, Lemma 20.4 the closure of the image of \( F \to Y \) has dimension at most \( \dim(Y) + \dim(Z) + 1 - n \). \( \square \)

**Lemma 23.4.** Let \( V \) be a vector space. Let \( B \subset \mathbf{P}(V) \) be a closed subvariety of codimension \( \geq 2 \). Let \( p \in \mathbf{P}(V) \) be a closed point, \( p \not\in B \). Then there exists a line \( \ell \subset \mathbf{P}(V) \) with \( \ell \cap B = \emptyset \). Moreover, these lines sweep out an open subset of \( \mathbf{P}(V) \).
**Proof.** Consider the image of $B$ under the projection $r_p : \mathbb{P}(V) \to \mathbb{P}(W_p)$. Since $\dim(W_p) = \dim(V) - 1$, we see that $r_p(B)$ has codimension $\geq 1$ in $\mathbb{P}(W_p)$. For any $q \in \mathbb{P}(V)$ with $r_p(q) \not\in r_p(B)$ we see that the line $\ell = \overline{pq}$ connecting $p$ and $q$ works. □

**Lemma 23.5.** Let $V$ be a vector space. Let $G = \text{PGL}(V)$. Then $G \times \mathbb{P}(V) \to \mathbb{P}(V)$ is doubly transitive.

**Proof.** Omitted. Hint: This follows from the fact that $\text{GL}(V)$ acts doubly transitive on pairs of linearly independent vectors. □

**Lemma 23.6.** Let $k$ be a field. Let $n \geq 1$ be an integer and let $x_{ij}, 1 \leq i, j \leq n$ be variables. Then

$$\det \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ x_{n1} & \cdots & \cdots & x_{nn} \end{pmatrix}$$

is an irreducible element of the polynomial ring $k[x_{ij}]$.

**Proof.** Let $V$ be an $n$ dimensional vector space. Translating into geometry the lemma signifies that the variety $C$ of non-invertible linear maps $V \to V$ is irreducible. Let $W$ be a vector space of dimension $n - 1$. By elementary linear algebra, the morphism

$$\text{Hom}(W, V) \times \text{Hom}(V, W) \to \text{Hom}(V, V), \quad (\psi, \varphi) \mapsto \psi \circ \varphi$$

has image $C$. Since the source is irreducible, so is the image. □

Let $V$ be a vector space of dimension $n + 1$. Set $E = \text{End}(V)$. Let $E^\vee = \text{Hom}(E, C)$ be the dual vector space. Write $P = P(E^\vee)$. There is a canonical linear map

$$V \to V \otimes_C E^\vee = \text{Hom}(E, V)$$

sending $v \in V$ to the map $g \mapsto g(v)$ in $\text{Hom}(E, V)$. Recall that we have a canonical map $E^\vee \to \Gamma(P, \mathcal{O}_P(1))$ which is an isomorphism. Hence we obtain a canonical map

$$\psi : V \otimes \mathcal{O}_P \to V \otimes \mathcal{O}_P(1)$$

of sheaves of modules on $P$ which on global sections recovers the given map. Recall that a projective bundle $P(E)$ is defined as the relative Proj of the symmetric algebra on $\mathcal{E}$, see Constructions, Definition 21.1. We are going to study the rational map between $P(V \otimes \mathcal{O}_P(1))$ and $P(V \otimes \mathcal{O}_P)$ associated to $\psi$. By Constructions, Lemma 16.10 we have a canonical isomorphism

$$P(V \otimes \mathcal{O}_P) = P \times P(V)$$

By Constructions, Lemma 20.1 we see that

$$P(V \otimes \mathcal{O}_P(1)) = P(V \otimes \mathcal{O}_P) = P \times P(V)$$

Combining this with Constructions, Lemma 18.1 we obtain

$$P \times P(V) \supset U(\psi) \xrightarrow{r_\psi} P \times P(V)$$

(23.6.1)

To understand this better we work out what happens on fibres over $P$. Let $g \in E$ be nonzero. This defines a nonzero map $E^\vee \to C$, hence a point $[g] \in P$. On the other
hand, \( g \) defines a \( \mathbb{C} \)-linear map \( g : V \to V \). Hence we obtain, by Constructions, Lemma \[11.1\] a map

\[
P(V) \supset U(g) \xrightarrow{r_g} P(V)
\]

What we will use below is that \( U(g) \) is the fibre \( U(\psi)_{[g]} \) and that \( r_g \) is the fibre of \( r_\psi \) over the point \([g]\). Another observation we will use is that the complement of \( U(g) \) in \( P(V) \) is the image of the closed immersion

\[
P(\text{Coker}(g)) \to P(V)
\]

and the image of \( r_g \) is the image of the closed immersion

\[
P(\text{Im}(g)) \to P(V)
\]

**Lemma 23.7.** With notation as above. Let \( X, Y \) be closed subvarieties of \( P(V) \) which intersect properly such that \( X \neq P(V) \). There exists a line \( \ell \subset P \) such that

1. \([id_V] \in \ell\),
2. \([g] \in \ell \) for all \([g] \in \ell\),
3. \( g(X) \) intersects \( Y \) properly for all \([g] \in \ell\).

**Proof.** Let \( B \subset P \) be the set of “bad” points, i.e., those points \([g]\) that violate either (2) or (3). Note that \([id_V] \notin B\) by assumption. Moreover, \( B \) is closed. Hence it suffices to prove that \( \dim(B) \leq \dim(P) - 2 \) (Lemma \[23.3\]).

First, consider the open \( G = \text{PGL}(V) \subset P \) consisting of points \([g]\) such that \( g : V \to V \) is invertible. Since \( G \) acts doubly transitively on \( P(V) \) (Lemma \[23.5\]) we see that

\[
T = \{(x, y, [g]) \mid x \in X, y \in Y, [g] \in G, r_g(x) = y\}
\]

is a locally trivial fibration over \( X \times Y \) with fibre equal to the stabilizer of a pair of points in \( G \). Hence \( T \) is a variety. Observe that the fibre of \( T \to G \) over \([g]\) is \( r_g(X) \cap Y \). The morphism \( T \to G \) is surjective, because any translate of \( X \) intersects \( Y \) (Varieties, Lemma \[23.3\]). Since the dimensions of fibres of a dominant morphism of varieties do not jump in codimension 1 (Varieties, Lemma \[20.4\]) we conclude that \( B \cap G \) has codimension \( \geq 2 \).

Next we look at the complement \( Z = P \setminus G \). This is an irreducible variety because the determinant is an irreducible polynomial (Lemma \[23.6\]). Thus it suffices to prove that \( B \) does not contain the generic point of \( Z \). For a general point \([g] \in Z\) the cokernel \( V \to \text{Coker}(g) \) has dimension 1, hence \( U(g) \) is the complement of a point. Since \( X \neq P(V) \) we see that for a general \([g] \in Z\) we have \( X \subset U(g) \). Moreover, the morphism \( r_g|_X : X \to r_g(X) \) is finite, hence \( \dim(r_g(X)) = \dim(X) \). On the other hand, for such a \( g \) the image of \( r_g \) is the closed subspace \( H = P(\text{Im}(g)) \subset P(V) \) which has codimension 1. For general point of \( Z \) we see that \( H \cap Y \) has dimension 1 less than \( Y \) (compare with Varieties, Lemma \[34.3\]). Thus we see that we have to show that \( r_g(X) \) and \( H \cap Y \) intersect properly in \( H \). For a fixed choice of \( H \), we can by postcomposing \( g \) by an automorphism, move \( r_g(X) \) by an arbitrary automorphism of \( H = P(\text{Im}(g)) \). Thus we can argue as above to conclude that the intersection of \( H \cap Y \) with \( r_g(X) \) is proper for general \( g \) with given \( H = P(\text{Im}(g)) \).

Some details omitted. \(\square\)
24. Moving Lemma

The moving lemma states that given an $r$-cycle $\alpha$ and an $s$-cycle $\beta$ there exists \( \alpha', \alpha' \sim_{\text{rat}} \alpha \) such that $\alpha'$ and $\beta$ intersect properly (Lemma 24.3). See [Sam56], [Che58a], [Che58b]. The key to this is Lemma 24.1; the reader may find this lemma in the form stated in [Ful98, Example 11.4.1] and find a proof in [Rob72].

**Lemma 24.1.** Let $X \subset \mathbb{P}^N$ be a nonsingular closed subvariety. Let $n = \dim(X)$ and $0 \leq d, d' < n$. Let $Z \subset X$ be a closed subvariety of dimension $d$ and $T_i \subset X$, $i \in I$ be a finite collection of closed subvarieties of dimension $d'$. Then there exists a subvariety $C \subset \mathbb{P}^N$ such that $C$ intersects $X$ properly and such that

\[
C : X = Z + \sum_{j \in J} m_j Z_j
\]

where $Z_j \subset X$ are irreducible of dimension $d$, distinct from $Z$, and

\[
\dim(Z_j \cap T_i) \leq \dim(Z \cap T_i)
\]

with strict inequality if $Z$ does not intersect $T_i$ properly in $X$.

**Proof.** Write $\mathbb{P}^N = \mathbb{P}(V_N)$ so $\dim(V_N) = N + 1$ and set $X_N = X$. We are going to choose a sequence of projections from points

\[
\begin{align*}
\pi_N & : \mathbb{P}(V_N) \setminus \{p_N\} \to \mathbb{P}(V_{N-1}), \\
\pi_{N-1} & : \mathbb{P}(V_{N-1}) \setminus \{p_{N-1}\} \to \mathbb{P}(V_{N-2}), \\
\vdots \\
\pi_{n+1} & : \mathbb{P}(V_{n+1}) \setminus \{p_{n+1}\} \to \mathbb{P}(V_n)
\end{align*}
\]

as in Section 23. At each step we will choose $p_N, p_{N-1}, \ldots, p_{n+1}$ in a suitable Zariski open set. Pick a closed point $x \in Z \subset X$. For every $i$ pick closed points $x_i \in T_i \cap Z$, at least one in each irreducible component of $T_i \cap Z$. Taking the composition we obtain a morphism

\[
\pi = (\pi_{n+1} \circ \cdots \circ \pi_N)|_X : X \to \mathbb{P}(V_n)
\]

which has the following properties

1. $\pi$ is finite,
2. $\pi$ is étale at $x$ and all $x_i$,
3. $\pi|_Z : Z \to \pi(Z)$ is an isomorphism over an open neighbourhood of $\pi(x_i)$,
4. $T_i \cap \pi^{-1}(\pi(Z)) = (T_i \cap Z) \cup E_i$ with $E_i \subset T_i$ closed and $\dim(E_i) \leq d + d' + 1 - (n + 1) = d + d' - n$.

It follows in a straightforward manner from Lemmas 23.1, 23.2, and 23.3 and induction that we can do this; observe that the last projection is from $\mathbb{P}(V_{n+1})$ and that $\dim(V_{n+1}) = n + 2$ which explains the inequality in (4).

Let $C \subset \mathbb{P}(V_N)$ be the scheme theoretic closure of $\left(\pi_{n+1} \circ \cdots \circ \pi_N\right)^{-1}(\pi(Z))$. Because $\pi$ is étale at the point $x$ of $Z$, we see that the closed subscheme $C \cap X$ contains $Z$ with multiplicity 1 (local calculation omitted). Hence by Lemma 17.2 we conclude that

\[
C : X = [Z] + \sum m_j [Z_j]
\]

for some subvarieties $Z_j \subset X$ of dimension $d$. Note that

\[
C \cap X = \pi^{-1}(\pi(Z))
\]
set theoretically. Hence $T_i \cap Z_j \subset T_i \cap \pi^{-1}(Z)) \subset T_i \cap Z \cup E_i$. For any irreducible component of $T_i \cap Z$ contained in $E_i$ we have the desired dimension bound. Finally, let $V$ be an irreducible component of $T_i \cap Z_j$ which is contained in $T_i \cap Z$. To finish the proof it suffices to show that $V$ does not contain any of the points $x_{it}$, because then $\dim(V) < \dim(Z \cap T_i)$. To show this it suffices to show that $x_{it} \notin Z_j$ for all $i, t, j$.

Set $Z' = \pi(Z)$ and $Z'' = \pi^{-1}(Z')$, scheme theoretically. By condition (3) we can find an open $U \subset P(V_\alpha)$ containing $\pi(x_{it})$ such that $\pi^{-1}(U) \cap Z$ is an isomorphism. In particular, $Z \to Z'$ is a local isomorphism at $x_{it}$. On the other hand, $Z'' \to Z'$ is étale at $x_{it}$ by condition (2). Hence the closed immersion $Z \to Z''$ is étale at $x_{it}$ (Morphisms, Lemma 34.18). Thus $Z = Z''$ in a Zariski neighbourhood of $x_{it}$ which proves the assertion. \qed

The actual moving is done using the following lemma.

**Lemma 24.2.** Let $C \subset P^N$ be a closed subvariety. Let $X \subset P^N$ be subvariety and let $T_i \subset X$ be a finite collection of closed subvarieties. Assume that $C$ and $X$ intersect properly. Then there exists a closed subvariety $C' \subset P^N \times P^1$ such that

1. $C' \to P^1$ is dominant,
2. $C'_0 = C$ scheme theoretically,
3. $C'$ and $X \times P^1$ intersect properly,
4. $C'_{\infty}$ properly intersects each of the given $T_i$.

**Proof.** Write $P^N = P(V)$ so $\dim(V) = N + 1$. Let $E = \text{End}(V)$. Let $E^\vee = \text{Hom}(E, C)$. Set $P = P(E^\vee)$ as in Lemma 23.7. Choose a general line $\ell \subset P$ passing through $\text{id}_V$. Set $C' \subset \ell \times P(V)$ equal to the closed subscheme having fibre $r_g(C)$ over $[g] \in \ell$. More precisely, $C'$ is the image of

$$\ell \times C \subset P \times P(V)$$

under the morphism (23.6.1). By Lemma 23.7 this makes sense, i.e., $\ell \times C \subset U(\psi)$. The morphism $\ell \times C \to C'$ is finite and $C'_{[g]} = r_g(C)$ set theoretically for all $[g] \in \ell$. Parts (1) and (2) are clear with $0 = [\text{id}_V] \in \ell$. Part (3) follows from the fact that $r_g(C)$ and $X$ intersect properly for all $[g] \in \ell$. Part (4) follows from the fact that a general point $\infty = [g] \in \ell$ is a general point of $P$ and for such point $r_g(C) \cap T$ is proper for any closed subvariety $T$ of $P(V)$ (see proof of Lemma 23.7). Some details omitted. \qed

**Lemma 24.3.** Let $X$ be a nonsingular projective variety. Let $\alpha$ be an $r$-cycle and $\beta$ be an $s$-cycle on $X$. Then there exists an $r$-cycle $\alpha'$ such that $\alpha' \sim_{\text{rat}} \alpha$ and such that $\alpha'$ and $\beta$ intersect properly.

**Proof.** Write $\beta = \sum n_i[T_i]$ for some subvarieties $T_i \subset X$ of dimension $s$. By linearity we may assume that $\alpha = [Z]$ for some irreducible closed subvariety $Z \subset X$ of dimension $r$. We will prove the lemma by induction on the maximum $e$ of the integers

$$\dim(Z \cap T_i)$$

The base case is $e = r + s - \dim(X)$. In this case $Z$ intersects $\beta$ properly and the lemma is trivial.

Induction step. Assume that $e > r + s - \dim(X)$. Choose an embedding $X \subset P^N$ and apply Lemma 24.1 to find a closed subvariety $C \subset P^N$ such that $C \cdot X =
With definitions as above we show that the intersection product is well defined. Next, apply Lemma 24.2 to \( C, X, T_i \) to find \( C' \subset \mathbb{P}^N \times \mathbb{P}^1 \). Let \( \gamma = C' \cdot X \times \mathbb{P}^1 \) viewed as a cycle on \( X \times \mathbb{P}^1 \). By Lemma 22.2 we have

\[
[Z] + \sum m_j[Z_j] = \text{pr}_{X,s}(\gamma \cdot X \times 0)
\]

On the other hand the cycle \( \gamma_{\infty} = \text{pr}_{X,s}(\gamma \cdot X \times \infty) \) is supported on \( C' \cap X \) hence intersects \( \beta \) transversally. Thus we see that \( [Z] \sim_{\text{rat}} - \sum m_j[Z_j] + \gamma_{\infty} \) by Lemma 17.1. Since by induction each \( [Z_j] \) is rationally equivalent to a cycle which properly intersects \( \beta \) this finishes the proof. □

### 25. Intersection products and rational equivalence

**Lemma 25.1.** Let \( X \) be a nonsingular variety. Let \( W \subset X \times \mathbb{P}^1 \) be an \((s + 1)\)-dimensional subvariety dominating \( \mathbb{P}^1 \). Let \( W_a, \) resp. \( W_b \) be the fibre of \( W \to \mathbb{P}^1 \) over \( a, \) resp. \( b \). Let \( V \) be a \( r \)-dimensional subvariety of \( X \) such that \( V \) intersects both \( W_a \) and \( W_b \) properly. Then \( [V] \cdot [W_a] \sim_{\text{rat}} [V] \cdot [W_b] \).

**Proof.** We have \( [W_a] = \text{pr}_{X,s}(W \cdot X \times a) \) and similarly for \( [W_b] \), see Lemma 17.1. Thus we reduce to showing

\[
V \cdot \text{pr}_{X,s}(W \cdot X \times a) \sim_{\text{rat}} V \cdot \text{pr}_{X,s}(W \cdot X \times b).
\]

Applying the projection formula Lemma 22.1 we get

\[
V \cdot \text{pr}_{X,s}(W \cdot X \times a) = \text{pr}_{X,s}(V \times \mathbb{P}^1 \cdot (W \cdot X \times a))
\]

and similarly for \( b \). Thus we reduce to showing

\[
\text{pr}_{X,s}(V \times \mathbb{P}^1 \cdot (W \cdot X \times a)) \sim_{\text{rat}} \text{pr}_{X,s}(V \times \mathbb{P}^1 \cdot (W \cdot X \times b))
\]

If \( V \times \mathbb{P}^1 \) intersects \( W \) properly, then associativity for the intersection multiplicities (Lemma 20.1) gives \( V \times \mathbb{P}^1 \cdot (W \cdot X \times a) = (V \times \mathbb{P}^1 \cdot W) \cdot X \times a \) and similarly for \( b \). Thus we reduce to showing

\[
\text{pr}_{X,s}((V \times \mathbb{P}^1 \cdot W) \cdot X \times a) \sim_{\text{rat}} \text{pr}_{X,s}((V \times \mathbb{P}^1 \cdot W) \cdot X \times b)
\]

which is true by Lemma 17.1.

The argument above does not quite work. The obstruction is that we do not know that \( V \times \mathbb{P}^1 \) and \( W \) intersect properly. We only know that \( V \) and \( W_a \) and \( V \) and \( W_b \) intersect properly. Let \( Z_i, i \in I \) be the irreducible components of \( V \times \mathbb{P}^1 \cap W \). Then we know that \( \dim(Z_i) \geq r + 1 + s + 1 - n - 1 = r + s + 1 - n \) where \( n = \dim(X) \), see Lemma 13.4. Since we have assumed that \( V \) and \( W_a \) intersect properly, we see that \( \dim(Z_i, a) = r + s - n \) or \( Z_i, a = \emptyset \). On the other hand, if \( Z_i, a \neq \emptyset \), then \( \dim(Z_i) \geq \dim(Z_i) - 1 = r + s - n \). It follows that \( \dim(Z_i) = r + s + 1 - n \) if \( Z_i \) meets \( X \times a \) and in this case \( Z_i \to \mathbb{P}^1 \) is surjective. Thus we may write \( I = I' \sqcup I'' \) where \( I' \) is the set of \( i \in I \) such that \( Z_i \to \mathbb{P}^1 \) is surjective and \( I'' \) is the set of \( i \in I \) such that \( Z_i \) lies over a closed point \( t_i \in \mathbb{P}^1 \) with \( t_i \neq a \) and \( t_i \neq b \). Consider the cycle

\[
\gamma = \sum_{i \in I'} e_i[Z_i]
\]

where we take

\[
e_i = \sum_p (-1)^p \text{length}_{\mathcal{O}_{X \times \mathbb{P}^1, Z_i}} \text{Tor}_p^{\mathcal{O}_{X \times \mathbb{P}^1, Z_i}}(\mathcal{O}_{V \times \mathbb{P}^1, Z_i}, \mathcal{O}_{W, Z_i})
\]
We will show that \( Y \) can be used as a replacement for the intersection product of \( V \times P^1 \) and \( W \).

We will show this using associativity of intersection products in exactly the same way as above. Let \( U = P^1 \setminus \{ t_i, i \in I'' \} \). Note that \( X \times a \) and \( X \times b \) are contained in \( X \times U \). The subvarieties

\[
V \times U, \quad W_U, \quad X \times a \quad \text{of} \quad X \times U
\]

intersect transversally pairwise by our choice of \( X \) in \( X \) as cycles on \( X \) as above. Let

\[
\begin{align*}
W & \quad \text{be a nonsingular projective variety. Let} \quad \alpha, \beta \in X, \\
V & \quad \text{be an irreducible component of} \quad V \times U (W \cdot X) = \dim(V \cap W_a) \quad \text{has the expected dimension. Thus we see that}
\end{align*}
\]

\[
V \times U \cdot (W_U \cdot X \times a) = (V \times U \cdot W_U) \cdot X \times a
\]

as cycles on \( X \times U \) by Lemma \[20.1\]. By construction \( \gamma \) restricts to the cycle \( V \times U \cdot W_U \) on \( X \times U \). Trivially, \( V \times P^1 \cdot (W \cdot X \times a) \) restricts to \( V \times U \cdot (W_U \cdot X \times a) \) on \( X \times U \). Hence

\[
V \times P^1 \cdot (W \cdot X \times a) = \gamma \cdot X \times a
\]

as cycles on \( X \times P^1 \) (because both sides are contained in \( X \times U \) and are equal after restricting to \( X \times U \) by what was said before). Since we have the same for \( b \) we conclude

\[
V \cdot [W_a] = \text{pr}_{X,*}(V \times P^1 \cdot (W \cdot X \times a)) = \text{pr}_{X,*}(\gamma \cdot X \times a) \sim_{rat} \text{pr}_{X,*}(\gamma \cdot X \times b) = \text{pr}_{X,*}(V \times P^1 \cdot (W \cdot X \times b)) = V \cdot [W_b]
\]

The first and the last equality by the first paragraph of the proof, the second and penultimate equalities were shown in this paragraph, and the middle equivalence is Lemma \[17.1\].

**Theorem 25.2.** Let \( X \) be a nonsingular projective variety. Let \( \alpha, \beta \in X \), \( \gamma \) be an \( r \), resp. \( s \) cycle on \( X \). Assume that \( \alpha \) and \( \beta \) intersect properly so that \( \alpha \cdot \beta \) is defined. Finally, assume that \( \alpha \sim_{rat} 0 \). Then \( \alpha \cdot \beta \sim_{rat} 0 \).

**Proof.** Pick a closed immersion \( X \subset P^N \). By linearity it suffices to prove the result when \( \beta = [Z] \) for some \( s \)-dimensional closed subvariety \( Z \subset X \) which intersects \( \alpha \) properly. The condition \( \alpha \sim_{rat} 0 \) means there are finitely many \( (r+1) \)-dimensional closed subvarieties \( W_{i,a} \subset X \times P^1 \) such that

\[
\alpha = \sum [W_{i,a}]_r - [W_{i,b}]_r
\]

for some pairs of points \( a_i, b_i \) of \( P^1 \). Let \( W_{i,a}^t \) and \( W_{i,b}^t \) be the irreducible components of \( W_{i,a} \) and \( W_{i,b} \). We will use induction on the maximum \( d \) of the integers

\[
\dim(Z \cap W_{i,a}^t), \quad \dim(Z \cap W_{i,b}^t)
\]

The main problem in the rest of the proof is that although we know that \( Z \) intersects \( \alpha \) properly, it may not be the case that \( Z \) intersects the “intermediate” varieties \( W_{i,a}^t \) and \( W_{i,b}^t \) properly, i.e., it may happen that \( d > r + s - \dim(X) \).

Base case: \( d = r + s - \dim(X) \). In this case all the intersections of \( Z \) with the \( W_{i,a}^t \) and \( W_{i,b}^t \) are proper and the desired result follows from Lemma \[25.1\] because it applies to show that \( [Z] \cdot [W_{i,a}]_r \sim_{rat} [Z] \cdot [W_{i,b}]_r \) for each \( i \).
Lemma 24.3 and Theorem 25.2 also hold for nonsingular quasi-projective varieties with the same proof. The only change is that one needs to prove the following version of the moving Lemma 24.1: Let \( X \subset \mathbb{P}^N \) be a closed subvariety. Let \( n = \dim(X) \) and \( 0 \leq d, d' < n \). Let \( X^{\text{reg}} \subset X \) be the open subset of nonsingular points. Let \( Z \subset X^{\text{reg}} \) be a closed subvariety of dimension \( d \) and \( T_i \subset X^{\text{reg}}, i \in I \) be a finite collection of closed subvarieties of dimension \( d' \). Then there exists a subvariety \( C \subset \mathbb{P}^N \) such that \( C \) intersects \( X \) properly and such that

\[
(C \cdot X)|_{X^{\text{reg}}} = Z + \sum_{j \in J} m_j Z_j
\]

Putting everything together we have

\[
[C P^N \times \mathbb{P}^1 = \sum n_k[E_k] \text{ for some subvarieties } E_k \subset X \times \mathbb{P}^1 \text{ of dimension } s + 1. \text{ Note that } n_k > 0 \text{ for all } k \text{ by Proposition 19.3.}
\]

By Lemma 22.2 we have

\[
[Z] + \sum m_j[Z_j] = \sum n_k[E_{k,0}]_s
\]

Since \( E_{k,0} \subset C \cap X \) we see that \( [E_{k,0}]_s \) and \( \alpha \) intersect properly. On the other hand, the cycle

\[
\gamma = \sum n_k[E_{k,\infty}]_s
\]

is supported on \( C_{\infty} \cap X \) and hence properly intersects each \( W_{i,a}, W_{i,b} \). Thus by the base case and linearity, we see that

\[
\gamma \cdot \alpha \sim_{\text{rat}} 0
\]

As we have seen that \( E_{k,0} \) and \( E_{k,\infty} \) intersect \( \alpha \) properly Lemma 25.1 applied to \( E_k \subset X \times \mathbb{P}^1 \) and \( \alpha \) gives

\[
[E_{k,0}] \cdot \alpha \sim_{\text{rat}} [E_{k,\infty}] \cdot \alpha
\]

Putting everything together we have

\[
[C \cdot \alpha = (\sum n_k[E_{k,0}]_s - \sum m_j[Z_j]) \cdot \alpha
\]

\[
\sim_{\text{rat}} \sum n_k[E_{k,0}] \cdot \alpha \text{ (by induction hypothesis)}
\]

\[
\sim_{\text{rat}} \sum n_k[E_{k,\infty}] \cdot \alpha \text{ (by the lemma)}
\]

\[
= \gamma \cdot \alpha
\]

\[
\sim_{\text{rat}} 0 \text{ (by base case)}
\]

This finishes the proof. \( \square \)

0B61 **Remark 25.3.** Lemma 24.3 and Theorem 25.2 also hold for nonsingular quasi-projective varieties with the same proof. The only change is that one needs to prove the following version of the moving Lemma 24.1: Let \( X \subset \mathbb{P}^N \) be a closed subvariety. Let \( n = \dim(X) \) and \( 0 \leq d, d' < n \). Let \( X^{\text{reg}} \subset X \) be the open subset of nonsingular points. Let \( Z \subset X^{\text{reg}} \) be a closed subvariety of dimension \( d \) and \( T_i \subset X^{\text{reg}}, i \in I \) be a finite collection of closed subvarieties of dimension \( d' \). Then there exists a subvariety \( C \subset \mathbb{P}^N \) such that \( C \) intersects \( X \) properly and such that

\[
(C \cdot X)|_{X^{\text{reg}}} = Z + \sum_{j \in J} m_j Z_j
\]
where $Z_j \subset X^{reg}$ are irreducible of dimension $d$, distinct from $Z$, and

$$\dim(Z_j \cap T_i) \leq \dim(Z \cap T_i)$$

with strict inequality if $Z$ does not intersect $T_i$ properly in $X^{reg}$.

26. Chow rings

Let $X$ be a nonsingular projective variety. We define the intersection product

$$A_r(X) \times A_s(X) \to A_{r+s-\dim(X)}(X), \quad (\alpha, \beta) \mapsto \alpha \cdot \beta$$

as follows. Let $\alpha \in Z_r(X)$ and $\beta \in Z_s(X)$. If $\alpha$ and $\beta$ intersect properly, we use the definition given in Section 17. If not, then we choose $\alpha \sim_{rat} \alpha'$ as in Lemma 24.3 and we set

$$\alpha \cdot \beta = \text{class of } \alpha' \cdot \beta \in A_{r+s-\dim(X)}(X)$$

This is well defined and passes through rational equivalence by Theorem 25.2. The intersection product on $A^*(X)$ is commutative (this is clear), associative (Lemma 20.1) and has a unit $[X] \in A^{\dim(X)}(X)$.

Often it is convenient to use $A^c(X) = A_{\dim(X)-c}(X)$ to denote the group of codimension $c$ cycles modulo rational equivalence. The intersection product defines a product

$$A^k(Y) \times A^l(Y) \to A^{k+l}(X)$$

which is commutative, associative, and has a unit $1 = [X] \in A^0(X)$.

27. Pullback for a general morphism

Let $f : X \to Y$ be a morphism of nonsingular projective varieties. We define

$$f^* : A_k(Y) \to A_{k+\dim X-\dim Y}(X)$$

by the rule

$$f^*(\alpha) = \text{pr}_X^*(\Gamma_f \cdot \text{pr}_Y^*(\alpha))$$

where $\Gamma_f \subset X \times Y$ is the graph of $f$. Note that in this generality, it is defined only on cycle classes and not on cycles. With the notation $A^*$ introduced in Section 26 we may think of pullback as a map

$$f^* : A^*(Y) \to A^*(X)$$

in other words, it is a map of graded abelian groups.

Lemma 27.1. Let $f : X \to Y$ be a morphism of nonsingular projective varieties. The pullback map on chow groups satisfies:

1. $f^* : A^*(Y) \to A^*(X)$ is a ring map,
2. $(g \circ f)^* = f^* \circ g^*$ for a composable pair $f, g$,
3. the projection formula holds: $f_*(\alpha) \cdot \beta = f_*(\alpha \cdot f^*\beta)$, and
4. if $f$ is flat then it agrees with the previous definition.

Proof. All of these follow readily from the results above.

For (1) it suffices to show that $\text{pr}_{X,*}(\Gamma_f \cdot \alpha \cdot \beta) = \text{pr}_{X,*}(\Gamma_f \cdot \alpha) \cdot \text{pr}_{X,*}(\Gamma_f \cdot \beta)$ for cycles $\alpha, \beta$ on $X \times Y$. If $\alpha$ is a cycle on $X \times Y$ which intersects $\Gamma_f$ properly, then it is easy to see that

$$\Gamma_f \cdot \alpha = \Gamma_f \cdot \text{pr}_X^*(\text{pr}_{X,*}(\Gamma_f \cdot \alpha))$$
as cycles because $\Gamma_f$ is a graph. Thus we get the first equality in
\[
\pr_{X,*}(\Gamma_f \cdot \alpha \cdot \beta) = \pr_{X,*}(\Gamma_f \cdot \pr_X^*(\pr_{X,*}(\Gamma_f \cdot \alpha)) \cdot \beta)
\]
\[
= \pr_{X,*}(\pr_X^*(\pr_{X,*}(\Gamma_f \cdot \alpha)) \cdot (\Gamma_f \cdot \beta))
\]
\[
= \pr_{X,*}(\Gamma_f \cdot \alpha) \cdot \pr_{X,*}(\Gamma_f \cdot \beta)
\]
the last step by the projection formula in the flat case (Lemma \[22.1\]).

If $g : Y \to Z$ then property (2) follows formally from the observation that

\[
\Gamma = \pr_X^* \times Y \Gamma_f \cdot \pr_Y \times Z \Gamma_g
\]
in $Z_*(X \times Y \times Z)$ where $\Gamma = \{(x, f(x), g(f(x)))\}$ and maps isomorphically to $\Gamma_{g \circ f}$ in $X \times Z$. The equality follows from the scheme theoretic equality and Lemma \[14.3\]

For (3) we use the projection formula for flat maps twice

\[
f_*(\alpha \cdot \pr_{X,*}(\Gamma_f \cdot \pr_Y^*(\beta))) = f_*(\pr_{X,*}(\pr_X^* \alpha \cdot \Gamma_f \cdot \pr_Y^*(\beta)))
\]
\[
\quad = \pr_Y^*(\pr_X^* \alpha \cdot \Gamma_f \cdot \pr_Y^*(\beta))
\]
\[
\quad = \pt_{qY,*}(\pr_X^* \alpha \cdot \Gamma_f) \cdot \beta
\]
\[
\quad = f_*(\alpha) \cdot \beta
\]
where in the last equality we use the remark on graphs made above. This proves (3).

Property (4) rests on identifying the intersection product $\Gamma_f \cdot \pr_Y^* \alpha$ in the case $f$ is flat. Namely, in this case if $V \subseteq Y$ is a closed subvariety, then every generic point $\xi$ of the scheme $f^{-1}(V) \cong \Gamma_f \cap \pr_Y^{-1}(V)$ lies over the generic point of $V$. Hence the local ring of $\pr_Y^{-1}(V) = X \times V$ at $\xi$ is Cohen-Macaulay. Since $\Gamma_f \subseteq X \times Y$ is a regular immersion (as a morphism of smooth projective varieties) we find that

\[
\Gamma_f \cdot \pr_Y^*[V] = [\Gamma_f \cap \pr_Y^{-1}(V)]_d
\]
with $d$ the dimension of $\Gamma_f \cap \pr_Y^{-1}(V)$, see Lemma \[16.5\]. Since $\Gamma_f \cap \pr_Y^{-1}(V)$ maps isomorphically to $f^{-1}(V)$ we conclude.

\[\square\]

28. Pullback of cycles

Suppose that $X$ and $Y$ be nonsingular projective varieties, and let $f : X \to Y$ be a morphism. Suppose that $Z \subseteq Y$ is a closed subvariety. Let $f^{-1}(Z)$ be the scheme theoretic inverse image:

\[
\begin{array}{ccc}
  f^{-1}(Z) & \to & Z \\
    \downarrow & & \downarrow \\
    X & \to & Y
  \end{array}
\]
is a fibre product diagram of schemes. In particular $f^{-1}(Z) \subseteq X$ is a closed subscheme of $X$. In this case we always have

\[
\dim f^{-1}(Z) \geq \dim Z + \dim X - \dim Y.
\]
If equality holds in the formula above, then $f^*[Z] = [f^{-1}(Z)]_{\dim Z + \dim X - \dim Y}$ provided that the scheme $Z$ is Cohen-Macaulay at the images of the generic points of $f^{-1}(Z)$. This follows by identifying $f^{-1}(Z)$ with the scheme theoretic intersection of $\Gamma_f$ and $X \times Z$ and using Lemma \[16.5\]. Details are similar to the proof of part (4) of Lemma \[27.1\] above.
